ACKNOWLEDGMENT

The author wishes to acknowledge the assistance of Doctor E. E. Reid, Professor of Chemistry, Johns-Hopkins University, at whose suggestion this research topic was undertaken. To Doctor B. B. Wroth and Doctor W. S. Taylor of the Department of Chemistry, Georgia School of Technology, he expresses his appreciation for their valuable suggestions and criticism.
A STUDY OF THE PREPARATION OF THIOLBENZOIC ACID
AND BENZOYL DISULFIDE

Introduction

Thiolbenzoic acid ($C_6H_5COSH$) and its oxidation product, benzoyl disulfide ($C_6H_5COSCSSCOC_6H_5$), have long been known, but have been little worked on and deserve further study. Their preparation by simple methods would prove to be foundation for work on substituted thiolbenzoic acids. The purpose of this paper is to describe efforts toward production of these two substances by methods heretofore untried.

Thiolbenzoic Acid

Historical. — Thiolbenzoic acid has been prepared by a wide variety of methods. The most important of these follow: (1) by the action of carbon oxysulfide on phenyl magnesium bromide in ether $^1$; (2) by shaking a solution of benzoyl chloride in water-alcoholic potash with sulfur $^2$; (3) by boiling benzoic acid-phenyl ester or benzoic acid anhydride with alcoholic KSH $^3$; (4) by the action of benzoyl chloride on an alcoholic solution of $K_2S$ $^4$; (5) by the action

of benzoyl disulfide on alcoholic KSH \(^5\); (6) by the action of a water solution of potash on a boiling alcoholic solution of benzoyl disulfide \(^6\); (7) by dissolving benzoyl disulfide in an alcoholic solution of KSH \(^7\); (8) on the addition of NH\(_3\) to a solution of dibenzoyl disulfide in chloroform \(^8\); (9) by the action of benzoyl chloride on an alcoholic solution of KSH, with subsequent acidification \(^9\).

Experimental. — The method of Kym \(^9\) was followed in the preparation of thiolbenzoic acid for purposes of comparison. 20 gms. benzoyl chloride were added to a cold alcoholic solution of 20 gms. KOH saturated with H\(_2\)S, the precipitated KCl filtered off and the filtrate evaporated to dryness on a water bath. The yield of the reddish crude potassium thiolbenzoate, 27 gms., compared favorably with that of Kym. The salt was dissolved in the least possible amount of water and the free acid precipitated by the addition of 3N HCl. The equations are as follows:

\[
\text{KOH} + \text{H}_2\text{S} \rightarrow \text{KSH} + \text{H}_2\text{O}.
\]

\[
\text{C}_8\text{H}_7\text{O} + \text{KSH} \rightarrow \text{C}_8\text{H}_7\text{O} - \text{K} + \text{HCl}.
\]

(9) Kym, Berichte, 32, 3533 (1899), footnote.
\[
\text{KOH} + \text{HCl} \rightarrow \text{KCl} \downarrow + \text{H}_2\text{O}.
\]
\[
\bigcirc - \text{C}_2\text{O}_5\text{S} - \text{K} + \text{HCl} \rightarrow \bigcirc - \text{C}_2\text{O}_5\text{S} - \text{H} + \text{KCl}.
\]

It appears as a yellow oil which solidifies in the cold and melts at 24°. After cooling the solution, the solid was filtered off by suction. A difficulty is its ready oxidation in air to benzoyl disulfide, as shown by the equation:

\[
2 \bigcirc - \text{C}_2\text{O}_5\text{S} - \text{H} + \frac{1}{2}\text{O}_2 \rightarrow \bigcirc - \text{C}_2\text{O}_5\text{S} - \text{S} - \text{C}_2\text{O}_5\text{S} + \text{H}_2\text{O}.
\]

There is no obvious reason for using the hydrosulfide instead of the more easily obtainable sulfide. Sodium salts are preferable to those of potassium. The alcohol is objectionable as it forms more or less ethyl benzoate. It was suggested that 350 gms. crystalline \( \text{Na}_2\text{S} \) be dissolved in 700 cc. \( \text{H}_2\text{O} \) and 140 gms. benzoyl chloride added, with intense mechanical stirring. On completion of this reaction the solution was acidified with \( \text{HCl} \), when the thiolbenzoic acid should separate as a yellowish oil. The reactions are shown by the following equations:

\[
\bigcirc - \text{C}_2\text{O}_5\text{Cl} + \text{Na}_2\text{S} \rightarrow \bigcirc - \text{C}_2\text{O}_5\text{S} - \text{Na} + \text{NaCl}.
\]

\[
\bigcirc - \text{C}_2\text{O}_5\text{S} - \text{Na} + \text{HCl} \rightarrow \bigcirc - \text{C}_2\text{O}_5\text{S} - \text{H} + \text{NaCl}.
\]

Until the reaction worked well, only one-tenth of the above quantities were to be used.

A number of runs were made in an effort to carry out these reactions. The temperature was kept low in each case, the agitations being carried out between 0° and 40° C. At the
end of the agitation the solution was always of a reddish-
yellow color and a small quantity of a yellowish oil settled
to the bottom. Acidification, however, did not produce the
thiolbenzoic acid sought except in traces. Varying either the
acid or the strength of the acid used had no effect on the re-
sult. Since a 35% excess of \( \text{Na}_2\text{S} \) was used, the first action
with the acid was the liberation of \( \text{H}_2\text{S} \) gas according to the
equation:

\[
\text{Na}_2\text{S} + 2\text{HCl} \rightarrow 2\text{NaCl} + \text{H}_2\text{S}.
\]

Addition of the acid to faint acidity produced no further
visible change, while a large excess of acid yields a volumi-
nous yellowish-white precipitate which had a melting point of
117-9°.

It was thought that this yellowish material was
sulfur, since sulfur may have a melting point at practically
any point between 113° and 120°, depending upon the form in
which it is precipitated. Later conclusions led to the belief
that it was very impure benzoyl disulfide (melting point, 128°),
resulting from the rapid oxidation of any thiolbenzoic acid
which was formed. An attempt was made to determine the exact
nature of the material. Any benzoyl disulfide formed would
have been contaminated with HCl, NaCl, and benzoic acid formed
by hydrolysis of benzoyl chloride, indicated by the equation:

\[
\text{C}^\circ\text{Cl} + \text{H}_2\text{O} \rightarrow \text{C}^\circ\text{OH} + \text{HCl}.
\]
Treatment with NaOH would result in the formation of the soluble sodium benzoate and NaCl, as follows:

\[ \text{HC}^\equiv\text{O} + \text{NaOH} \rightarrow \text{C}^\equiv\text{O}^-\text{Na} + \text{H}_2\text{O}. \]

\[ \text{HCl} + \text{NaOH} \rightarrow \text{NaCl} + \text{H}_2\text{O}. \]

Subsequent washing with water should remove these soluble materials. However, on treatment with aqueous NaOH (3N) practically all of the unknown dissolved. This destroyed the belief that the material was benzoyl disulfide. Acidification of the solution resulted in the reprecipitation of the substance, which on further purification by repeated washing was identified by its appearance, chemical properties and melting point to be benzoic acid. The small amount of material unattacked by NaOH proved to be sulfur. Identical results were secured in every case.

Conclusions. — Either thiolbenzoic acid was not formed in the reactions or the conditions were not favorable for its appearance. Instead of reacting with Na₂S present in the solution, the benzoyl chloride hydrolyzed, producing benzoic acid. Varying the temperature at which the reaction is carried out through the range of 0° to 40° had no effect on the final result. Further efforts to obtain thiolbenzoic acid by the proposed method were abandoned, repeated experiments having all led to the same conclusions.
Benzoyl Disulfide

Historical. — Benzoyl disulfide has been prepared in a number of ways. Some of the most typical follow: (1) by the action of PbS on an ethereal solution of benzoyl chloride; (2) by boiling benzoyl chloride with sodium hydrosulfite; (3) by the action of benzoyl chloride on N,N'-dimethyl thiuram disulfide or N,N'-diethyl thiuram disulfide in alcoholic-alkaline solution; (4) by heating benzoic acid anhydride in a stream of dry H₂S at 130°; (5) by the oxidation of thiolbenzoic acid in ether or CS₂ solution or in alcoholic solution in the air; (6) from potassium thiolbenzoate on treating a water solution with a solution of iodine in KI or with excess CuSO₄ solution, by treating a water solution with K₃Fe(CN)₆ or by treating an alcoholic solution with FeCl₃.

Experimental. — A new, more direct method was successfully utilized in the production of benzoyl disulfide. 24 gms. crystalline Na₂S·9H₂O were dissolved in 14 cc. H₂O, 32 gms. finely-powdered rhombic sulfur added, and the liquid warmed until all was dissolved, keeping from contact with air.

insofar as possible. This gives a reddish solution of Na₂S₂. The solution was cooled to 5° and 26 gms. benzoyl chloride added, with intense mechanical stirring. A yellowish solid resembling sulfur very closely separated out at once. This solid dissolves in any excess benzoyl chloride which escapes hydrolysis to form a pasty mass or separates out if hydrolysis is complete.

The pasty mass is a source of trouble whenever it appears. It was thought advisable first to dilute the benzoyl chloride with several volumes of carbon disulfide in order to keep the materials liquid, benzoyl disulfide being very soluble in CS₂. When all of the benzoyl chloride had dissolved, the heavier carbon disulfide layer was separated and evaporated to dryness on a water bath. However, difficulty was encountered in the operation because of the extreme inflammability of the carbon disulfide. Even when all the carbon disulfide has been vaporized, the excess benzoyl chloride remaining is very difficult to remove. The solid-liquid mixture now present is the same as that which would be secured if no carbon disulfide had been present when the initial reaction was carried out. Accordingly, the reaction was carried out with no carbon disulfide being added to the entering benzoyl chloride. Aqueous NaOH was used in the separation of the resulting materials. The benzoyl disulfide secured will be very impure. Excess benzoyl chloride, any unused Na₂S, and possibly some sulfur which might be set free during the course of the reaction, will be mixed with and adsorbed by the benzoyl disulfide. With NaOH,
the benzoyl chloride and benzoic acid were converted into the water-soluble sodium benzoate. The following equations explain the reactions:

\[
\begin{align*}
\text{C}_{6}\text{H}_{5}\text{Cl} + 2\text{NaOH} &\rightarrow \text{C}_{6}\text{H}_{5}\text{O}^-\text{Na}^+ + \text{NaCl} + \text{H}_2\text{O} \\
\text{C}_{6}\text{H}_{5}\text{OH} + \text{NaOH} &\rightarrow \text{C}_{6}\text{H}_{5}\text{O}^-\text{Na}^+ + \text{H}_2\text{O}
\end{align*}
\]

Filtration and washing with water will aid in the purification of the crude benzoyl disulfide.

An agitation with no carbon disulfide being present gave a solid material whose melting point was 117-8°C. Treatment with aqueous (3N) NaOH in the manner described immediately above increased the purity of the substance to such an extent that the melting point was elevated to 123°C. Sulfur and benzoyl disulfide are the only solids of the general appearance and properties of the unknown material that could conceivably be present; the highest melting point that is possessed by any form of sulfur is 120°C, whereas the melting point of benzoyl disulfide has been reported as 128°C.1,10 Benzoyl sulfide, C6H5COSCOC6H5, and thiolbenzoic acid, C6H5COSH, are automatically eliminated because their melting points are 48°C and 24°C, respectively. Repeated treatment (three additional digestions) with NaOH increased the melting point of the solid to 128°C (cor.), the previously reported temperature given as the melting point of the pure substance. The pure benzoyl disulfide is of a pale yellowish-white color, a much lighter tint than that of sulfur. Thus it has been proved
that the reactions must proceed according to the equations:

$$\text{Na}_2\text{S} + \text{S} \rightarrow \text{Na}_2\text{S}_2.$$  

$$2\text{O}_2 + \text{Na}_2\text{S}_2 \rightarrow 2\text{S}_2\text{O}_3 + 2\text{NaCl}.$$  

To confirm the presence of benzoyl disulfide, the solid secured was submitted to a careful analysis for sulfur content. A combustion in a Parr bomb was carried out according to the standard method. Sulfur was oxidized to $\text{SO}_4$ and precipitated as $\text{BaSO}_4$. The precipitate was filtered off, using a Gooch crucible with an asbestos mat, and ignited to constant weight. The crucible having previously been heated to constant weight, the percentage of sulfur was calculated. The equations explaining the method are:

$$\text{S} + 4[\text{O}] \text{ (oxidation)} \rightarrow \text{SO}_4.$$  

$$\text{SO}_4 + \text{BaCl}_2 \rightarrow \text{BaSO}_4 \downarrow + 2\text{Cl}^-.$$  

A blank run was made to determine the percentage of sulfur in the reagents used. Then a combustion analysis was made, using the material thought to be benzoyl disulfide. The results are summarized in the table below:

</table>

It will be noted that comparable checks were obtained. The average of the two samples of the supposed benzoyl disulfide, 23.65%, is 0.39% higher than the theoretical, but is close enough to show beyond doubt that the material actually is benzoyl disulfide.

A series of runs have been made to determine the optimum temperature for the reaction used in the production of benzoyl disulfide. The same quantities of materials were used as above. The results are as follows:

</tbody>
</table>
Temp. Wt. crude | M.F. crude | Wt. pure | Theoretical yield
benz. dis. | benz. dis. | benz. dis. | yield (M.F. 127-8°)

90° | 12.62 gm. | 112° | 5.87 gm. | 25.43 gm. | 23%
100° | 11.71 " | 112° | 4.33 " | 25.43 " | 17%

From the percentage yields it is obvious that the temperature most favorable to the reaction is in the neighborhood of 30°. Of course the weight of the crude benzoyl disulfide secured in each instance is necessarily a variable quantity and cannot be used in estimating the extent to which the reaction goes to completion.

Conclusions. — Benzoyl disulfide has been prepared by the action of benzoyl chloride on an aqueous solution of sodium disulfide. The crude material must be carefully purified by repeated digestions with aqueous NaOH. The optimum temperature for the reaction has been found to be about 30° C.

Suggestions for Further Work

The method outlined above has given us a good method for the direct preparation of benzoyl disulfide. This has never been reduced to thiolbenzoic acid, but it should not be difficult. It was planned to carry out a series of reductions, the results to be incorporated in this paper, but lack of time forced its postponement.

It is suggested that iron turnings or iron powder be used with dilute acetic acid or sulfuric acid, and
granulated zinc and tin with the same acids. An alkaline reducing mixture to be employed might be zinc and caustic soda. Another excellent reducing agent is arsenious acid with an excess of rather strong caustic soda.
