CHAPTER I

INTRODUCTION

The purpose of this paper is to study the foundations of the theory of generalized random variables of the form $\mathcal{X} : \Omega \to \mathcal{X}$, where $\Omega$ is a probability space and $\mathcal{X}$ is a topological measurable space. Many random phenomena in physics and engineering have outcomes which are not numbers, but vectors, matrices, functions, or operators. Thus it is desirable to extend the theory of probability to include such phenomena. A considerable amount of research has been devoted to this extension in recent years, for example in papers by SEGAL, BLACKWELL, DUBINS, HANS, NEDOMA, DRIML and HANS, SPACEK, and many others. A discussion of much of this recent work and an extensive bibliography can be found in the recently published book of GRENANDER. But the prerequisites for understanding the literature are formidable. Thus in this paper an attempt is made to present those parts of topology and functional analysis which will facilitate an understanding of the current literature.

Assumed to begin with are a knowledge of elementary set theory and logic, the properties of the real and complex number systems, and the basic theory of functions of a real variable. Chapter II is devoted to the presentation of the fundamental algebraic and topological concepts, and contains many of the definitions to be used throughout the remaining chapters.

In Chapter III the necessary concepts and tools from measure theory and integration are developed, first for real and complex valued
functions, then the theory is extended to Banach valued functions.
The theory of the Bochner integral presented here is a modified version
of that found in HILLE and PHILLIPS; namely the domain measure space is
assumed to be $\sigma$-finite, and simple functions are used in the definition
of the Bochner integral instead of elementary functions. This makes it
possible to develop much of the theory without using the Hahn-Banach
Theorem, by using Egorov's Theorem and some of its consequences. The
necessary parts of Hilbert space theory are examined briefly at the end
of the chapter.

In Chapter IV the previously developed material is applied to
extend some of the most important theorems of classical probability
theory, from the real case to the Hilbert or Banach valued case. The
material on conditional expectations is mostly due to DRIML and HANS.

In the first four chapters, no essentially topological concepts
are used, except those which can be expressed in terms of sequential
convergence in a metric space. Chapter V is devoted to the development
of some of the functional analysis and topology which seems to be neces-
sary in reading the current literature on generalized random variables,
including the Hahn-Banach Theorem and the Tychonov Product Theorem and
some of their consequences. The concept of compactness is particularly
stressed here, since it is used extensively in Chapter VI.

In Chapter VI a generalization of the Kolmogorov Consistency
Theorem is proved, using topological methods and a slight modification
of Kolmogorov's proof as given in KOLMOGOROV [1], p. 29-33 and LOEVE,
p. 93. See also HALMOS [1], p. 212. The Consistency Theorem has been
generalized previously by SEGAL, BLACKWELL, and SPACEK; but these
results will not be examined here, since they were uncovered only after this paper had been almost completed. It will be noted only that the proof given here seems to be more direct and to use more elementary techniques, so that this version may be a special case of some of the others. The generalization proved here guarantees in particular the existence of random variables in a separable, complete pseudo-metric space which have preassigned, consistent joint distributions.

Concepts will be presented in an abstract, axiomatic form, usually without obvious intuitive motivation or description of applications.

There are several conventions with regard to notation and terminology which will be followed throughout. Sets will be denoted by capital letters $C$, and classes of sets by capital script letters $\mathcal{C}$. The index $n$ varies from 1 to $\infty$, $\lim a_n = \lim a_n$, and $\bigcup A_n = \bigcup_{n=1}^{\infty} A_n$ unless otherwise indicated; similarly for $m, k, j$. The word sum, used in connection with sets, means disjoint union, and finite or countable sums of sets $A_n$ will usually be denoted by $\sum A_n$ or $A_1 + A_2 + \ldots$ instead of $\bigcup A_n$; the use of this notation is intended to imply automatically that the sets $A_n$ are disjoint. Unqualified statements involving a variable $x$ in a space $X$ are understood to mean "for all $x \in X"$ or "for arbitrary fixed $x \in X"$; the meaning should always be clear from the context.

Names of references are capitalized, and multiple references by the same author are followed by numbers in square brackets. The references used most extensively are DRIML and HANS, HALMOS [1], [2], HILLE and PHILLIPS, KELLEY, KOLMOGOROV [1], [2], and LOEVE.
A complete list of symbols and abbreviations can be found in the Appendix.

In general, those theorems which are considered to be especially important, or which are generalizations of theorems in the literature, are given greater typographical emphasis.
In this chapter, the basic concepts to be used later will be introduced, and some of the relations between them will be examined. These basic concepts are:

1. **linear (vector) space and linear function**
2. **topological space and continuous function**
3. **measurable space and measurable function**

The algebraic concepts will be introduced first. A **groupoid** is a pair \((G, \ast)\) consisting of a nonempty set \(G\) and a binary operator \(\ast : G \times G \rightarrow G\). A **semigroup** is an associative groupoid \((G, \ast)\):

\[(a \ast b) \ast c = a \ast (b \ast c)\].

A **monoid** is a semigroup \((G, \ast)\) with an identity element \(i \in G\) such that \(i \ast a = a \ast i = a\) for all \(a \in G\); an element \(e \in G\) is a **unit** if there is an inverse element \(e^{-1} \in G\) such that \(e^{-1} \ast e = e \ast e^{-1} = i\). A **group** is a monoid \((G, \ast)\) such that every element in \(G\) is a unit; and an **Abelian group** is a commutative group:

\[a \ast b = b \ast a\].

A **ring** is a triple \((R, +, \ast)\) such that \((R, +)\) is an (additive) Abelian group with (additive) identity \(\theta\), \((R, \ast)\) is a semigroup, and the distributive laws hold:

\[a \ast (b + c) = a \ast b + a \ast c\],

\[(a + b) \ast c = a \ast c + b \ast c\].

A **field** (algebraic) is a ring \((F, +, \ast)\), with at least two elements, such that \((F - \{0\}, \ast)\) is an Abelian group with identity \(1\), where \(0\) is the additive identity. For the sake of convenience, groups, rings, and fields will be denoted simply by \(G, R, F, \ldots\).
respectively, whenever the binary operators are understood. The binary operator $+$ is called addition, and $*$ is called multiplication (or composition, or convolution). The product $a * b$ will usually be denoted simply by $ab$.

Suppose $G$ and $G'$ are two additive groupoids, and let $a : G \to G'$. (If $G = G'$, then $a$ is called an operator on $G$.) The function $a$ is said to be additive (groupoid homomorphism) iff

$$(1) \quad a(x + y) = ax + ay \quad (x, y \in G).$$

The concept of an additive function is very important in this paper.

If $a : R \to R'$, where $R$ and $R'$ are rings, then $a$ is said to be multiplicative iff

$$(2) \quad a(xy) = (ax)(ay) \quad (x, y \in G),$$

and $a$ is a ring homomorphism iff it is both additive and multiplicative. If $R, R'$ have multiplicative identities $1, 1'$ respectively and $a1 = 1' a$, then $a(1x) = ax = 1'(ax) = (a1)(ax)$; thus if $a$ is only additive, it is still true that (2) holds for some pairs $x, y$. If $R$ and $R'$ are commutative rings, then clearly $a(xy) = (ax)(ay)$ implies $a(yx) = (ay)(ax)$, and the relation $D_a = \{(x, y) \in G \times G : a(xy) = (ax)(ay)\}$ is symmetric. The elements $x, y \in G$ will be called $a$-independent iff $a(xy) = (ax)(ay)$. For commutative rings, this motion can obviously be generalized to a finite number of terms, and then corresponds exactly to the concept of independence in probability.

Consider now an arbitrary nonempty set $X$, and let $\mathcal{R}$ be a nonempty class of subsets of $X$ such that, if $A, B \in \mathcal{R}$, then

$$(1) \quad A \setminus B \in \mathcal{R},$$

$$(2) \quad A \cup B \in \mathcal{R}.$$
It follows that $\emptyset \in \mathcal{A}$ and $AB = A \cup B - (A^C \cup B^C) \in \mathcal{A}$. (Note: $A \cup B$ will be denoted by $A + B$ iff $AB = \emptyset$.) If the binary operation $\pm$ is defined by

$$A \pm B = AB^C + A^C B = (A - B) + (B - A),$$

then it follows that $A \pm B = B \pm A$, $(A \pm B) \pm C = A \pm (B \pm C)$, and $(A \pm B)C = AC \pm BC$. Therefore $(\mathcal{A}, \pm, \cap, \cup, -)$ is a ring, where $\emptyset$ is the zero element and the inverse of a set $A$ is $A$ itself. Conversely, if $\mathcal{A}$ is closed under $\pm$, $\cap$, and $\cup$, and $\mathcal{A}$ is closed under $\cap$, since $A \cup B = (A \pm B) + AB$. For this reason, $\mathcal{A}$ is called a (Boolean) ring of sets iff axioms (1) and (2) above are satisfied. A $\sigma$-ring is a nonempty class $\mathcal{J}$ which is closed under differences and countable unions (hence also countable intersections).

If $\zeta$ is any nonempty class of sets, $G$ is an additive Abelian group, and $\varphi : \zeta \rightarrow G$ is a set function, then $\varphi$ is additive iff $\varphi(A + B) = \varphi A + \varphi B$ whenever $A, B \in \zeta$, $AB = \emptyset$, and $A + B \in \zeta$; $\varphi$ is finitely additive iff $\varphi \left( \sum_{1}^{n} A_k \right) = \sum_{1}^{n} \varphi A_k$ whenever $A_k \in \zeta$, $A_j A_k = \emptyset$ $(j \neq k)$, and $\sum_{1}^{n} A_k \in \zeta$. If $\mathcal{A}$ is a ring, and $\varphi : \mathcal{A} \rightarrow G$ is additive, it follows that $\varphi(\emptyset) = 0$, $\varphi$ is finitely additive, $\varphi(A - B) = \varphi A - \varphi AB$, and $\varphi(A \cup B) = \varphi A + \varphi B + \varphi AB$ whenever $A, B \in \mathcal{A}$.

A linear space (vector space) is a pair $(G, F)$ consisting of an additive Abelian group $G$, with zero element $0$, and a field $F$ of operators on $G$, with zero element $0$ and unity element $1$, such that the following axioms are satisfied for $\alpha, \beta \in F$ and $x, y \in G$:

1. $\alpha(x + y) = \alpha x + \alpha y$ (the operators are additive)
2. $(\alpha + \beta)x = \alpha x + \beta x$ (operator addition law)
(3) \((a\beta)x = a(\beta x)\) (operator composition law)

(4) \(1x = x\) (the unity element \(1 \in F\) is the identity operator).

It follows from (1) and (2) that \(a\beta = 0x = \emptyset\). The elements of \(G\) are called "vectors," and the elements of \(F\) are called "scalars." A linear space \((X, F)\) will usually be denoted simply by \(X\). In this paper, \(F\) will always be either the real line \(R^1\) or the complex plane \(C^1\), and \(X\) will be called a real linear space or complex linear space accordingly.

Note that if \((X, C^1)\) is a complex linear space, then \((X, R^1)\) is a real linear space, but not conversely; e.g. \((C^1, C^1)\) is a complex linear space, \((C^1, R^1)\) is a real linear space, and \((R^1, R^1)\) is a real linear space, but \((R^1, C^1)\) is not a linear space. From now on, the scalar field \(F\) will be denoted by \(Z\), and may be either \(R^1\) or \(C^1\) unless otherwise specified.

If \(X\) and \(Y\) are two linear spaces with the same scalar field \(Z\), and \(T : X \rightarrow Y\) is a function, then \(T\) is a linear function iff

1. \(T(x + y) = Tx + Ty\) (\(T\) is additive)
2. \(T(ax) = a(Tx)\) (\(T\) is homogeneous).

In case \(X = Y\), \(T\) is called an operator, and in case \(Y = Z\), \(T\) is called a functional. If \(f : X \rightarrow Z\) and \(f(x)\) is real for all \(x\), then \(f\) is a sublinear functional iff

1. \(f(x + y) \leq f(x) + f(y)\) (\(f\) is subadditive)
2. \(f(ax) = a(fx)\) for \(a \geq 0\) (\(f\) is semihomogeneous).

If \(Z = R^1\), then clearly every linear functional is sublinear.

A topology is a nonempty class \(\mathcal{U}\) such that

1. \(U, V \in \mathcal{U} \Rightarrow UV \in \mathcal{U}\)
2. \(\mathcal{U} \subset \mathcal{U} \Rightarrow \bigcup \mathcal{U} = \bigcup_{V \in \mathcal{U}} V \in \mathcal{U}\)
By taking the empty class for $\mathcal{V}$ in (2), it follows that $\emptyset \in \mathcal{U}$, and by taking $\mathcal{V} = \mathcal{U}$ it follows that $\bigcup \mathcal{U} = \bigcup \mathcal{V} = \mathcal{V} \in \mathcal{U}$; the pair $(X, \mathcal{U})$ is called a topological space. Suppose $(\Omega, \mathcal{J})$ and $(X, \mathcal{U})$ are two topological spaces, and let $X : \Omega \rightarrow X$ be a function. Then $X$ is said to be $(\mathcal{J}, \mathcal{U})$-continuous iff

$$[X^{-1} U : U \in \mathcal{U}] = X^{-1} \mathcal{U} \subseteq \mathcal{J}$$

A topological space $(X, \mathcal{U})$ will usually be denoted simply by $X$; the sets $U$ in the topology $\mathcal{U}$ are called open sets, and

$$\mathcal{U}^c = \{U^c : U \in \mathcal{U}\}$$

is the class of all closed sets. It follows from DeMorgan's laws,

$$(\bigcap A_i)^c = \bigcup A_i^c, \quad (\bigcup A_i)^c = \bigcap A_i^c$$

that $\mathcal{U}^c$ is closed under finite unions and arbitrary intersections. Since $X^{-1} U^c = (X^{-1} U)^c$, it follows that a function $X : \Omega \rightarrow X$ is $(\mathcal{J}, \mathcal{U})$-continuous iff $X^{-1} \mathcal{U}^c \subseteq \mathcal{J}^c$.

A much more detailed discussion of the topological concepts introduced below can be found in KELLEY.

The interior of a set $A$ is the set

$$A^o = \{B : A \supseteq B \in \mathcal{U}\}$$

and is clearly the largest open set contained in $A$; thus $A$ is open iff $A = A^o$. It follows from the definition that $A^{oo} = A^o$, $(AB)^o = A^o B^o$, and $A \subseteq B \supseteq A^o \subseteq B^o$.

The closure of a set $A$ is the set

$$\overline{A} = \bigcap \{B : B \supseteq A \in \mathcal{U}\}$$

and $A$ is closed iff $A = \overline{A}$. It follows from the definition that $\overline{A}^{oo} = \overline{A}$, $(AB)^\circ = A^\circ B^\circ$, and $A \supseteq B \supseteq A^\circ \supseteq B^\circ$.
\[ A^\ominus = \bigcap \{ C : A \subseteq C \subseteq U^c \} \]

and is clearly the smallest closed set containing A; thus A is closed iff \( A = A^- \). It follows that

\[ A^\ominus = A^-, \quad (A \cup B)^\ominus = A^- \cup B^-, \text{ and } A \subseteq B \Rightarrow A^- \subseteq B^- . \]

A set \( V \) is a \textit{neighborhood} (nhd.) of a point \( x \) iff \( x \in V^o \), or equivalently iff there is an open set \( U \) such that \( x \in U \subseteq V \). Note that a nhd. need not be open. The class \( \mathcal{N}_x \) of all neighborhoods of a point \( x \) is called the \textit{neighborhood system} of \( x \). It follows that a set \( S \) is open iff it is a nhd. of each of its points:

\[ \mathcal{U} = \{ S : S \in \mathcal{N}_x \text{ for all } x \in S \} . \]

The following dual relations are consequences of the definitions of interior, closure, and neighborhood:

\[ A^0 = \{ x : A^c \subseteq V = \emptyset (V \subseteq A) \text{ for some } V \in \mathcal{N}_x \} . \]

\[ A^- = \{ x : AV \neq \emptyset \text{ for every } V \in \mathcal{N}_x \} . \]

\[ A^\ominus = A^0, \quad A^o = A^- , \quad A^c = A^0 . \]

For each \( x \), \( \mathcal{N}'_x = \{ V' = V - x : V \in \mathcal{N}_x \} \) is called the \textit{deleted} nhd. system of \( x \). Let

\[ A^L = \{ x : AV' \neq \emptyset \text{ for every } V' \in \mathcal{N}'_x \} . \]

The points in \( A^L \) are called \textit{limit points} of \( A \), and it follows that \( A \) is closed iff \( A^L \subseteq A \). Furthermore, \( A^- = A \cup A^L \) for every set \( A \).

A class \( \mathcal{M}_x \subseteq \mathcal{N}_x \) is a \textit{local base at} \( x \), or a base for \( \mathcal{N}_x \), iff
for every \( N \in \mathcal{N}_x \) there is an \( M \in \mathcal{M}_x \) such that \( x \in M \subseteq N \).

A filter is a nonempty class \( \mathcal{F} \) of nonempty sets such that

1. \( A, B \in \mathcal{F} \Rightarrow AB \in \mathcal{F} \)
2. \( A \supseteq B \in \mathcal{F} \Rightarrow A \in \mathcal{F} \)

A direction is a nonempty class \( \mathcal{D} \) of nonempty sets such that the intersection of two \( \mathcal{D} \) sets contains a \( \mathcal{D} \) set. It follows that every nhd. system \( \mathcal{N}_x \) is a filter, and every filter or local base is a direction.

A class \( \mathcal{I} \) is a base for a topology \( \mathcal{U} \) iff

\[
\mathcal{U} = \left\{ \bigcup \mathcal{B} : \mathcal{B} \subseteq \mathcal{I} \right\}
\]

If \( \mathcal{U} \) is a given topology, it follows that \( \mathcal{I} \) is a base for \( \mathcal{U} \) iff \( \mathcal{I} \subseteq \mathcal{U} \) and \( \mathcal{I}_x = \left\{ S : x \in S \in \mathcal{I} \right\} \) is a base for \( \mathcal{N}_x \) for all \( x \). On the other hand, if \( \mathcal{I} \) is a given class, then the class \( \mathcal{U} = \left\{ \bigcup \mathcal{D} : \mathcal{D} \subseteq \mathcal{I} \right\} \) is a topology on \( x \) iff \( \mathcal{I}_x \) is a direction for all \( x \in X \).

A topological space \( X \) is first countable \( (C_1) \) iff, for each \( x \in X \), there is a countable base \( \mathcal{N}_x = \left\{ M_n \right\} \) for \( \mathcal{N}_x \). If \( X \) is \( C_1 \), it follows that for each \( x \) there is a countable local base \( \left\{ M_n \right\} \) such that \( M_n \downarrow \); simply let \( M_n = \bigcap_{1}^{n} M_k \).

A topological space \( X \) is second countable \( (C_2) \) iff there is a countable base \( \mathcal{I} = \left\{ T_n \right\} \) for the topology \( \mathcal{U} \). Clearly every \( C_2 \) space is \( C_1 \).

A set \( D \subseteq X \) is dense in \( X \) iff \( D^- = X \), and \( X \) is separable iff there is a countable dense set \( D = \left\{ x_n \right\} \subseteq X \). Every \( C_2 \) space is separable. Simply choose a point \( x_n \in T_n \) for each \( n \), where \( \left\{ T_n \right\} \) is a countable base for \( \mathcal{U} \). Then for any \( x \) and any nhd \( U \) of \( x \), \( x_n \in T_n \subseteq U \) for some \( n \); thus \( x \in \left[x_n\right] \).

Two sets \( A, B \) are said to be (weakly) separated iff there exist
open sets $U, V \in \mathcal{U}$ such that

$$A \subseteq U^c \quad \text{and} \quad B \subseteq V^c.$$ 

The sum $A + B$ of two nonempty separated sets is called a separation, and a set $S$ is connected iff it cannot be written as a separation. If $A + B \supseteq C$, where $A + B$ is a separation and $C$ is connected, then either $A \supseteq C$ or $B \supseteq C$; for otherwise $AC + BC = C$ would be a separation.

Two sets $A, B$ are strongly separated iff there exist open sets $U, V$ such that $A \subseteq U$, $B \subseteq V$, and $UV = \emptyset$.

A top. space $X$ is $T_1$ iff every two distinct points are weakly separated (equivalently $[x]$ is closed for all $x$); and $X$ is Hausdorff $(T_2)$ iff every two distinct points are strongly separated. Clearly every $T_2$ space is $T_1$.

If $X$ is a nonempty set, then a metric or distance function on $X$ is a function $d : X \times X \to \mathbb{R}^+$ such that

1. $d(x, y) \leq d(x, z) + d(y, z)$
2. $d(x, x) = 0$
3. $d(x, y) = 0 \Rightarrow x = y$.

It follows from (1) and (2) that $d(x, y) = d(y, x) \geq 0$. If $d$ satisfies only (1) and (2), then $d$ is called a pseudo-metric (p-metric), and $(X, d)$ is called a p-metric space; $X$ is a metric space iff $d$ is a metric. For each $x \in X$ and $r > 0$, the set

$$S(x, r) = \{y : d(x, y) < r\}$$

is called the open $r$-sphere centered at $x$. Let

$$\mathcal{F} = [S(x, r) : x \in X, \ r > 0].$$
It follows from the triangle inequality (1) that \( J \) is a base for a topology \( U \) on \( x \), since \( J_x = \{ S \in J : x \in S \} \) is a direction for each \( x \in X \). The topology \( U \) is called the \textit{p-metric topology} generated by \( d \). A topological space \((X, U)\) is \textit{metrizable} (\textit{p-metrizable}) iff there exists a metric (p-metric) \( d \) such that \( U \) is the metric (p-metric) topology generated by \( d \). This metric (p-metric), if it exists, is not in general unique; in fact

\[
d'(x, y) = \frac{d(x, y)}{1 + d(x, y)} < 1, \quad d''(x, y) = \min[1, d(x, y)] \leq 1
\]

are metrics (p-metrics) which both generate the same topology as \( d \).

It follows easily that a p-metric space is metric iff the p-metric topology is \( T_1 \). Every metric space is Hausdorff. Every p-metric space is regular: for each \( x \), the class \( \eta_x U^c \) of all closed nhds. of \( x \) is a base for \( \eta_x \).

The \textit{trivial} topology on \( X \) is the topology \( U_0 = [\emptyset, X] \), and \((X, U_0)\) is a p-metric space with p-metric \( d_0(x, y) = 0 \). The \textit{discrete} topology on \( X \) is the topology \( U_1 \) such that \([x]\) is open for each \( x \in X \) (i.e. \( U_1 = \mathcal{B}(x) = [\text{all subsets of } X] \)), and is a metric space with metric \( d_1(x, y) = 1 \ (x \neq y), \quad d_1(x, x) = 0 \).

Every p-metric space is \( C_1 \), since for each \( x \),

\[
\eta_x = [S(x, r) : r > 0, \text{ rational}] \]

is a countable local base at \( x \). A p-metric space \( X \) is \( C_2 \) if it is separable; for if \( D = [x_n] \) is a countable dense set, then \( J = [S(x_n, q) : n = 1, 2, \ldots, q > 0, \text{ rational}] \) is a countable base for the metric topology \( U \). To see this, take any point \( x \in X \), and let \( U \) be any open set containing \( x \) and \( S(x, r) \) an open sphere such that \( S(x, r) \subseteq U \). Then \( x_n \in S(x, r/2) \) for some \( n \) since \([x_n] \)
is dense, and \( x \in S(x_n, q) \subseteq S(x, r) \) for \( d(x_n, x) < q < r/2 \). Metric spaces will be called \( M_1 \) spaces, and separable metric spaces will be called \( M_2 \) spaces. Thus \( M_1 \subseteq C_1 \) and \( M_2 \subseteq C_2 \).

A class \( \zeta \) is an open cover of a set \( S \) iff \( \zeta \subseteq U \) and \( S \subseteq \bigcup \zeta \). A top. space \( X \) will be called \( L_1 \) iff every open cover of \( X \) has a countable subcover, and \( X \) will be called \( L_2 \) iff every open cover of an arbitrary set \( S \subseteq X \) has a countable subcover. This terminology is used because of the following famous theorem.

**Lindelöf Theorem.** Every \( C_2 \) space is \( L_2 \). (Thus \( M_2 \subseteq C_2 \subseteq L_2 \)).

**Proof.** Let \( \zeta \subseteq U \) be an open cover of a set \( S \), and let \( [T_n] \) be a countable base for \( U \). For each \( U \in \zeta \), write \( U = \bigcup_{k} T_n(k, u) \). Then

\[
S = \bigcup_{U \in \zeta} \bigcup_{k} T_n(k, u) \] is countable, where \( T_{u_j} \subseteq U_j \) for \( j = 1, 2, \ldots \); hence \( [U_j] \subseteq \zeta \) is a countable subcover, since

\[
S \subseteq \bigcup_{U_{u_j}} \bigcup_{U_j}.
\]

A sequence \( [x_n] \) in a top. space \( X \) is said to converge to a point \( x (x_n \to x) \) iff, for each \( V \in \mathcal{N}_x \), there is a positive integer \( p = p(x, v) \) such that \( n \geq p \) \( x_n \in V \). A sequence \( [x_n] \) is said to be eventually in a set \( S \) iff there is a positive integer \( p = p_S \) such that \( n \geq p \) \( x_n \in S \). Thus \( x_n \to x \) iff \( x_n \) is eventually in every nhd. of \( x \).

If \( X \) is \( C_1 \), then the topology \( U \) can be completely described in terms of sequential convergence:

\[
A^0 = \{ x : x_n \to x \big| x_n \text{ is eventually in } A \} \\
A^- = \{ x : x_n \to x \text{ for some sequence } x_n \in A \}.
\]

Let \( (X, U) \) and \( (Y, V) \) be two top. spaces and \( f : X \to Y \). If \( X \) is \( C_1 \), then \( f \) is \((U, V)\)-continuous iff
To show this, suppose first that \( f \) is continuous, let \( x_n \to x \), and choose any nhd. \( V \) of \( fx \). Since \( f \) is continuous, there is a nhd. \( U \) of \( x \) such that \( fU \subseteq V \). But \( x_n \) is eventually in \( U \), hence \( fx_n \) is eventually in \( fU \subseteq V \). Now suppose \( f \) is not continuous. Then for some \( x \in X \), there is a nhd. \( V \) of \( fx \) such that \( U = f^{-1}V \) is not a nhd. of \( x \). Let \( \{M_n\}_n \) be a countable, decreasing local base at \( x \), and for each \( n \) choose \( x_n \in M_n \cap U^c \). Then \( x_n \to x \), but \( fx_n \in V^c \) for all \( n \), hence \( fx_n \nrightarrow fx \).

If \( X \) is a p-metric space, then clearly

\[
x_n \to x \Leftrightarrow d(x, x_n) \to 0.
\]

A sequence \( x_n \) in a p-metric space \( X \) is a Cauchy sequence iff

\[
d(x_m, x_n) \to 0 \quad (m, n \to \infty),
\]

and \( X \) is complete iff every Cauchy sequence in \( X \) converges to some point in \( X \). Complete metric spaces and separable complete metric spaces will be called \( \overline{M}_1 \) spaces and \( \overline{M}_2 \) spaces, respectively.

Note that limits are not in general unique in a p-metric space; but \( x_n \to x, x_n \to y \) implies \( d(x, y) = 0 \). Clearly limits are unique in a Hausdorff space.

If \( X \) is a linear space with zero vector \( \theta \), then a norm on \( X \) is a function \( \| \cdot \| : X \to \mathbb{R}^+ \) such that

1. \( \| \alpha x \| = |\alpha| \| x \| \)
2. \( \| x + y \| \leq \| x \| + \| y \| \)
3. \( \| x \| = 0 \Leftrightarrow x = \theta. \)
Here $|a|$ is the ordinary absolute value of $a$, and should not be confused with the norm of a vector, since $\alpha, \beta$ will always denote scalars and $x, y$ vectors. It follows from (1) that $|\theta| = 0$, and then (1) and (2) with $y = -x$ imply that $|x| \geq 0$.

A **normed linear space** (NLS) is a pair $(X, |\cdot|)$ consisting of a linear space $X$ and a norm on $X$. The function $d(x, y) = |x - y|$ is easily seen to be a metric, and generates a topology on $X$ called the norm topology. It is easy to see that the function $T : X \to X$ defined by $Tx = \alpha x + a$, where $\alpha \neq 0$, is a homeomorphism of $X$ onto $X$; i.e. $T$ is a 1-1 mapping of $X$ onto itself such that $T$ and $T^{-1}$ are both continuous.

If $T : X \to Y$ is an additive transformation, then $T$ is continuous on $X$ iff it is continuous at the origin $\theta$. For if $x_n \to \theta \Rightarrow Tx_n \to 0$, then $x_n \to x \Rightarrow x_n - x \to \theta$, hence

$$|Tx_n - Tx| = |T(x_n - x)| \to 0.$$  

Similarly, a subadditive functional $f : X \to \mathbb{Z}$ such that $f(\theta) = 0$ is continuous iff it is continuous at $\theta$, since

$$-f(x - x_n) \leq f(x_n) - f(x) \leq f(x_n - x).$$

A **field** on $X$ is a nonempty class $\zeta \subseteq \mathcal{F}(X)$ such that, if $A, B \in \zeta$, then

1. $A^c \in \zeta$
2. $AB \in \zeta$

A **$\sigma$-field** on $X$ is a nonempty class $\mathcal{B} \subseteq \mathcal{F}(X)$ such that, if $[A_n] \subseteq \zeta$, then
It follows by DeMorgan's laws that intersections can be replaced by unions in (2) and (2)_σ. Clearly every σ-field is a σ-ring and a field; and every field contains \( \emptyset = A \sigma^C \) and \( X = \emptyset^C \), and is a ring.

Note that if \( \xi \) is a field, then \((\xi, \oplus, \ominus, \cap)\) is a ring with unity element \( X \), but is not a field in the algebraic sense, except in the trivial case \( \xi_\sigma = [\emptyset, X] \); since in all other cases \( X \) is the only set with an inverse with respect to intersection. The term "field" in this paper will refer to a field of sets from now on, and algebraic fields will be called "scalar fields."

If \( \mathfrak{B} \) is a σ-field on \( X \), then the pair \((X, \mathfrak{B})\) is called a measurable space, and sets \( B \in \mathfrak{B} \) are called measurable sets, or events. Suppose \((\Omega, \mathfrak{A})\) and \((X, \mathfrak{B})\) are two measurable spaces, and let \( X : \Omega \to X \) be a function. Then \( X \) is called an \((\mathfrak{A}, \mathfrak{B})\)-measurable function iff

\[
[X^{-1}B : B \in \mathfrak{B}] = X^{-1}\mathfrak{B} \subseteq \mathfrak{A}.
\]

It follows easily that the intersection of any nonempty family of σ-fields is a σ-field. If \( \xi \) is any class of subsets of \( X \), then there is at least one σ-field on \( X \) containing \( \xi \); namely the class \( \mathfrak{G}(X) \) of all subsets of \( X \). By definition,

\[
\bar{\xi} = \cap [\mathfrak{B} : \xi \subseteq \mathfrak{B}, \mathfrak{B} \text{ is a } \sigma \text{-field}]
\]

is the smallest σ-field containing \( \xi \). It follows that \( \xi \) is a σ-field iff \( \xi = \bar{\xi} \), and that
Thus the operation of taking smallest $\sigma$-fields is similar to the operation of taking closures of sets in a topological space, except that the analogue of $(A \cup B)^- = A^- \cup B^-$ is not true since $\bar{\zeta} \cup \bar{\delta}$ is not in general a $\sigma$-field. However it is true that $\bar{\zeta \cup \delta} = \bar{\zeta \cup \delta}$.

Now suppose $X : \Omega \rightarrow X$, where $(\Omega, \mathcal{A})$ and $(X, \mathcal{B})$ are measurable spaces, and let $\zeta$ be any class such that $\mathcal{B} = \bar{\zeta}$. Then $X^{-1} \zeta \subseteq \mathcal{A}$ implies that $X$ is $(\mathcal{A}, \mathcal{B})$-measurable. For if $\mathcal{B}_1 = \{ B \in \mathcal{B} : X^{-1}B \in \mathcal{A} \}$, then $\mathcal{B}_1$ is a $\sigma$-field and $\zeta \subseteq \mathcal{B}_1$, hence $\mathcal{B} = \bar{\zeta} \subseteq \bar{\mathcal{B}_1} = \mathcal{B}_1$, which implies that $X^{-1} \mathcal{B} \subseteq \mathcal{A}$. Therefore, $X$ is $(\mathcal{A}, \bar{\zeta})$-measurable iff $X^{-1} \zeta \subseteq \mathcal{A}$.

A topological measurable (T.M.) space is a triple $(X, \mathcal{U}, \mathcal{B})$ such that $(X, \mathcal{U})$ is a topological space and $(X, \mathcal{B})$ is a measurable space. Suppose $(\Omega, \mathcal{I}, \mathcal{A})$ and $(X, \mathcal{U}, \mathcal{B})$ are two topological measurable spaces, and let $X : \Omega \rightarrow X$ be a function. Then $X$ is $(\mathcal{I}, \mathcal{U})$-continuous iff $X^{-1} \mathcal{U} \subseteq \mathcal{I}$ and $(\mathcal{A}, \mathcal{B})$-measurable iff $X^{-1} \mathcal{B} \subseteq \mathcal{A}$. Because of the properties of inverse functions, it is clear that $\mathcal{I}_0 = X^{-1} \mathcal{U}$ is a topology and $\mathcal{A}_0 = X^{-1} \mathcal{B}$ is a $\sigma$-field; they are respectively the smallest topology $\mathcal{I}_0$ on $\Omega$ such that $X$ is $(\mathcal{I}_0, \mathcal{U})$-continuous and the smallest $\sigma$-field $\mathcal{A}_0$ on $\Omega$ such that $X$ is $(\mathcal{A}_0, \mathcal{B})$-measurable. Furthermore, $\mathcal{U}_1 = \{ U : X^{-1} U \in \mathcal{I} \}$ is a topology on $X$ and $\mathcal{B}_1 = \{ B : X^{-1} B \in \mathcal{A} \}$ is a $\sigma$-field on $X$; they are respectively the largest topology $\mathcal{U}_1$ on $X$ such that $X$ is $(\mathcal{I}, \mathcal{U}_1)$-continuous and the largest $\sigma$-field $\mathcal{B}_1$ on $X$ such that $X$ is $(\mathcal{A}, \mathcal{B}_1)$-measurable.

Let $X : \Omega \rightarrow X$ and $f : X \rightarrow Y$ where $(Y, \mathcal{V}, \zeta)$ is a third
If $X$ is $(\mathcal{J}, \mathcal{U})$-continuous or $(\mathcal{A}, \mathcal{B})$-measurable, and $f$ is $(\mathcal{U}, \mathcal{V})$-continuous or $(\mathcal{B}, \mathcal{\zeta})$-measurable, then it follows easily that the composition $fX : \Omega \to Y$ is $(\mathcal{J}, \mathcal{U})$-continuous or $(\mathcal{A}, \mathcal{\zeta})$-measurable, respectively.

In many applications, it is desirable that all continuous functions be measurable. Suppose $X$ is continuous, so that $X^{-1} \mathcal{U} \subseteq \mathcal{J}$. If $\mathcal{A} \supseteq \mathcal{J}$ and $\mathcal{B} \subseteq \mathcal{U}$, then $X$ is measurable, since $X^{-1} \mathcal{U} \subseteq \mathcal{J}$ implies that $\mathcal{U} \subseteq \mathcal{B}_1 = [B : X^{-1} B \in \mathcal{A}]$, which implies that $\mathcal{B} \subseteq \mathcal{U} \subseteq \mathcal{A}$, hence $X^{-1} \mathcal{B} \subseteq \mathcal{A}$. Therefore, $\mathcal{A} \supseteq \mathcal{J}$ and $\mathcal{B} \subseteq \mathcal{U}$ imply that $(\mathcal{J}, \mathcal{U})$-continuous functions are $(\mathcal{A}, \mathcal{B})$-measurable.

In order to guarantee that compositions $fX$ of continuous functions $X : \Omega \to X$ and $f : X \to Y$ be measurable, it therefore suffices to assume that $\mathcal{A} \supseteq \mathcal{J}$, $\mathcal{B} = \mathcal{U}$, and $\mathcal{\zeta} \subseteq \mathcal{\overline{U}}$.

Suppose $[X_t : t \in T]$ is a nonempty family of nonempty sets, where $T$ is a nonempty index set. By the Axiom of Choice, there exists a function $x : T \to \bigcup_{t \in T} X_t$ such that

$$x_t = x(t) \in X_t, \quad t \in T.$$ 

The space of all such "choice" functions is denoted by $X^T = \prod_{t \in T} X_t$. Thus in particular if $X_t \in X$ for all $t \in T$, then $X^T = [x : T \to X]$. Note that the product space $X^T$ is by definition a space of functions $x$, which can also be thought of as "vectors" $x = (x_t : t \in T)$, where the $t^{\text{th}}$ component of $x$ is $x_t \equiv x(t)$.

If $X = (X_t : t \in T)$ is a family of functions $X_t : \Omega \to X_t$, then $X$ can also be thought of as a single "vector valued" function $X : \Omega \to X^T$, whose $t^{\text{th}}$ component function is the function $X_t$; thus
Let \( X(\omega) = (X_t(\omega) : t \in T) = (X(t, \omega) : t \in T) \) for each \( \omega \in \Omega \). Then 

\[ X_t = p_tX, \text{ where } p_t \text{ is the projection of } X^T \text{ onto its } t^{th} \text{ component space } X_t, \text{ defined by } p_t x = x_t, \quad t \in T. \]

If \( S \) is a nonempty set, then a relation in \( S \) means a subset \( \subset S \times S \), and \( a < b \) means \( (a, b) \in \). A partially ordered set is a pair \( (S, <) \) consisting of a nonempty set \( S \) and a relation \( < \) in \( S \) such that

1. \( a < b, \quad b < c \implies a < c \)
2. \( a < b, \quad b < a \quad \text{iff} \quad a = b \)

A partially ordered set \( (S, <) \) is said to be linearly ordered iff

3. \( a < b \) or \( b < a \) for all pairs \( a, b \in S \).

If \( (S, <) \) is a partially ordered set, \( A \subset S \), and \( b \in S \), then \( b \) is an upper bound for \( A \) iff \( a < b \) for all \( a \in A \); and \( b \) is a least upper bound for \( A \) iff it is an upper bound and \( b < b' \) for any other upper bound \( b' \). It follows from (2) that least upper bounds are unique whenever they exist. An element \( m \in S \) is maximal iff

\[ m < n \in S \implies m = n \]

A subset \( C \subset S \) is called a chain iff \( (C, <) \) is linearly ordered. The following famous lemma, which is equivalent to the Axiom of Choice, will be assumed as an axiom.

**Zorn's Lemma.** Let \( (X, <) \) be a partially ordered set. If every chain \( C \) in \( S \) has an upper bound, then \( S \) has a maximal element.

A lattice is a partially ordered set \( (S, <) \) such that every pair \( a, b \in S \) has a least upper bound (supremum) \( a \lor b \) and a greatest lower bound (infimum) \( a \land b \). Thus \( \lor \) and \( \land \) are binary operators on
S such that

(1) \( a < c, \ b < c \) iff \( a \lor b < c \)
(2) \( a > c, \ b > c \) iff \( a \land b > c \)

where \( a > c \) means \( c < a \).

It is also easy to see that the following relations hold:

(1)' \( a < b \) iff \( a \lor b = b, \ (a \lor b) \lor c = a \lor (b \lor c) \)
(2)' \( a < b \) iff \( a \land b = a, \ (a \land b) \land c = a \land (b \land c) \)

In fact (1) and (1)' are equivalent, and (2) and (2)' are equivalent. The binary operators \( \lor \) and \( \land \) are called lattice operators. Note that \((S, \lor)\) and \((S, \land)\) are Abelian semigroups. Some examples of lattices are \((\mathcal{K}, \subset, \cup, \cap)\), and \((\mathbb{R}, \leq, \max, \min)\), where \( \mathcal{K} \) is either a ring of sets or a topology, and \( \mathbb{R} \) is the real line. These lattices are in fact distributive:

\[
\begin{align*}
\land (b \lor c) &= (a \land b) \lor (b \land c) \\
\lor (b \land c) &= (a \lor c) \land (b \lor c).
\end{align*}
\]

A \( \sigma \)-lattice is a lattice \((S, \prec)\) such that every sequence \([a_n] \subset S\) which is bounded above has a least upper bound \( V a_n \), and every sequence \([b_n] \subset S\) which is bounded below has a greatest lower bound \( \land b_n \). Thus if \( \mathcal{S}_a \) is the class of all sequences in \( S \) which are bounded above, and \( \mathcal{S}_b \) is the class of all sequences in \( S \) which are bounded below, then \( V : \mathcal{S}_a \rightarrow S \) and \( \land : \mathcal{S}_b \rightarrow S \) are operators such that

(1) \( a_n < a' \) for all \( n \) iff \( V a_n < a' \)
(2) \( b_n > b' \) for all \( n \) iff \( \land b_n > b' \).

Examples of \( \sigma \)-lattices are \((\mathcal{K}, \subset, \cup, \cap)\) and \((\mathbb{R}, \leq, \sup, \inf)\).
where \( \mathcal{R} \) is a \( \sigma \)-ring and \( R \) is either the real line or the extended real line \( \overline{\mathbb{R}} = [\infty, \infty] \).

One of the basic concepts which is used in this paper is the concept of convergence. The concept of sequential convergence in a topological space has already been introduced. But another notion of convergence also seems to appear frequently; namely convergence in a \( \sigma \)-lattice.

Suppose \((S, <)\) is a \( \sigma \)-lattice, and let \( \mathcal{B} = \mathcal{B}_a \mathcal{B}_b \) be the class of all bounded sequences in \( S \). Define \( \bigwedge \bigvee a_n = \bigwedge_n \bigvee_{k \geq n} a_k \) and \( \bigvee \bigwedge a_n = \bigvee_n \bigwedge_{k \geq n} a_k \) for \([a_n] \in \mathcal{B}\). Then since \( \bigvee_{j \geq m} a_j < \bigvee_{k \geq n} a_k \) for all \( m, n \), it follows that \( \bigwedge \bigvee a_j < \bigvee_{k \geq n} a_k \) for all \( n \), hence

\[
\bigvee \bigwedge a_m = \bigvee_m \bigwedge_{j \geq m} a_j < \bigvee_n \bigwedge_{k \geq n} a_k = \bigvee \bigwedge a_n.
\]

By definition, a sequence \([a_n] \in \mathcal{B}\) is said to converge to an element \( a \in S \) (\( a_n \to a, \lim a_n = a \)) iff

\[
\bigwedge \bigvee a_n = \bigvee \bigwedge a_n = a.
\]

Note that, to show that a sequence \([a_n] \in \mathcal{B}\) converges, it suffices to show that \( \bigwedge \bigvee a_n < \bigvee \bigwedge a_n \). In particular if \([a_n] \in \mathcal{B}\) and \( a_n \uparrow (a_n < a_{n+1} \text{ for all } n) \), then \( a_n = \bigwedge_{k \geq n} a_k \), thus \( \bigvee_{j \geq m} a_j = \bigvee a_n = \bigvee_{k \geq n} a_k \) implies \( \bigwedge a_n = \bigvee a_n = \bigwedge a_n \); similarly, if \( a_n \downarrow (a_n > a_{n+1}) \), then \( \lim a_n = \bigwedge a_n \). If \( a_n = a \) for all \( n \), then clearly \( \lim a_n = a \).

A function \( \varphi : S \to X \), where \( S \) is a \( \sigma \)-lattice and \( X \) is either a topological space or a \( \sigma \)-lattice, is said to be continuous at a point \( a \in S \) iff
\(a_n \rightarrow a\) in \(S \sqsupset \varphi(a_n) \rightarrow \varphi(a)\) in \(X\).

If \(a_n \uparrow a \sqsupset \varphi(a_n) \rightarrow \varphi(a)\), then \(\varphi\) is said to be **continuous from below** at \(a\), and if \(a_n \downarrow a \sqsupset \varphi(a_n) \rightarrow \varphi(a)\), then \(\varphi\) is said to be **continuous from above** at \(a\).

If \(\varphi : S \rightarrow X\), where \(S\) and \(X\) are both \(\tau\)-lattices, then \(\varphi\) is said to be **monotone** (increasing) iff \(a < b\) in \(S \sqsupset \varphi(a) < \varphi(b)\) in \(X\). It follows that a monotone function is continuous iff it is continuous from above and from below. To show this, let \(a_n \rightarrow a\), and note that

\[
a_n = \bigvee_{k \geq n} a_k \downarrow a \quad \text{and} \quad \bigwedge_{k \geq n} a_k \uparrow a.
\]

Hence,

\[
a_n < a_n' \sqsupset \varphi(a_n) < \varphi(a_n') \sqsupset \bigwedge \varphi(a_n) < \bigvee \varphi(a_n') = \varphi(a)
\]

by continuity from above. Similarly, \(\bigvee \bigwedge \varphi(a_n) \geq \varphi(a)\), hence

\[
\bigwedge \bigvee \varphi(a_n) < \varphi(a) < \bigvee \bigwedge \varphi(a_n).
\]

This concept of continuity is very important in later chapters.
CHAPTER III

MEASURES AND INTEGRALS

In this chapter, the basic parts of measure theory and integration which are used in probability theory will be developed. For a more complete discussion of this material, see HALMOS [1], LOEVE, and HILLE and PHILLIPS. Throughout the chapter, \((\Omega, \mathcal{A})\) is an arbitrary measurable space; and \(X\) is a NLS with scalar field \(\mathbb{Z}\), norm topology \(\mathcal{U}\), and Borel \(\sigma\)-field \(\mathcal{B} = \mathcal{U}\). In many cases \(X = \mathbb{R}^r\) or \(C^r\).

As noted in the preceding chapter, the concepts of additive function and continuous functions on a \(\sigma\)-lattice are extremely important.

Let \(\phi : \zeta \rightarrow X\) be a set function on a class \(\zeta \subset \mathcal{F}(\Omega)\) containing the empty set. Then \(\phi\) is \(\sigma\)-additive iff

\[A_n \in \zeta, \Sigma A_n \in \zeta (A_m A_n = \emptyset, m \neq n) \implies \phi \Sigma A_n = \Sigma \phi A_n.\]

If \(\phi\) is either additive or \(\sigma\)-additive, it follows that \(\phi(\emptyset) = \emptyset\). If \(\phi\) is \(\sigma\)-additive, then it is called an \(X\)-valued measure on \(\zeta\). Only the case \(X = \mathbb{Z}\) will be considered in this chapter; in this case a scalar valued measure \(\phi\) is called a real measure or a complex measure according as \(\mathbb{Z} = \mathbb{R}^r\) or \(\mathbb{Z} = C^r\). A real measure \(\phi\) is a measure iff \(\phi \geq 0\). If \(\phi \geq 0\) and \(\phi\) is finitely additive, then \(\phi\) is called a content. If \(\Omega \in \zeta\), then a probability on \(\zeta\) is a measure \(P\) on \(\zeta\) with \(P\Omega = 1\).

In the case of real measures, the value \(\infty\) is sometimes allowed, but never the value \(-\infty\).

Let \(\phi : \zeta \rightarrow \overline{\mathbb{R}}\) be a set function on a class \(\zeta\) such that

\[-\infty < \phi A \leq \infty,\]

and consider \(A_n \in \zeta\). Then \(\phi\) is said to be
(1) continuous from below iff \( A_n \uparrow A \in \zeta \triangleright \varphi A = \lim A_n \)

(2) continuous from above iff \( A_n \downarrow A \in \zeta \triangleright \varphi A_1 < \infty \triangleright \varphi A = \lim A_n \)

(3) continuous iff \( \varphi \) is continuous from above and from below.

Note that if \( \varphi A < \infty \) for all \( A \in \zeta \), \( \varphi \) is monotone, and \( \zeta \) is a \( \sigma \)-ring (hence also a \( \sigma \)-lattice), then this definition of continuity is equivalent to the definition of a continuous function on a \( \sigma \)-lattice given in the previous chapter.

Suppose now that \( \zeta \) is a nonempty class which is closed under finite sums and proper differences, so that if \( A_1, A_2 \in \zeta \), then
\[ A_1A_2 = \emptyset \triangleright A_1 + A_2 \in \zeta \text{ and } A_1 \supset A_2 \triangleright A_1 - A_2 \in \zeta. \]
In particular this will be true if \( \zeta \) is a ring. The following theorem is very important, and is probably used in this paper more than any other single theorem.

**Continuity Theorem.** Let \( \zeta \) be a class which is closed under finite sums and proper differences, and suppose \( \varphi : \zeta \rightarrow (-\infty, \infty] \) is additive.

(a) Then \( \sigma \)-additivity is equivalent to continuity from below, and continuity from below implies continuity from above.

(b) If \( \varphi \) is finite, then \( \varphi \) is continuous (\( \sigma \)-additive) iff it is continuous at \( \emptyset \).

**Proof.** (a) Suppose first that \( \varphi \) is continuous from below, and let \( A = \sum A_n \in \zeta \), \( B_n \downarrow B \in \zeta \), where \( A_n, B_n \in \zeta \) and \( \varphi B_n < \infty \) (hence \( \varphi B_n < \infty \) for all \( n \)).

Then \[ \sum_{1}^{n} A_k \uparrow A \text{ implies } \sum_{1}^{n} \varphi A_k \rightarrow \varphi A; \text{ and } B_1 - B_n \uparrow B_1 - B \] implies \( \varphi B_1 - \varphi B_n \rightarrow \varphi B_1 - \varphi B \), which implies \( \varphi B_n \rightarrow \varphi B \). Therefore \( \varphi \) is \( \sigma \)-additive and continuous from above.
Now suppose \( \varphi \) is \( \sigma \)-additive, and let \( A_n \uparrow A \in \mathcal{C} \) and \( A_0 = \emptyset \).

Then \( A = \sum(A_n - A_{n-1}) \) implies \( \varphi A = \sum\varphi(A_n - A_{n-1}) = \lim \sum^n_1(\varphi A_k - \varphi A_{k-1}) = \lim \varphi A_n \), hence \( \varphi \) is continuous from below.

(b) Suppose \( \varphi \) is finite and continuous at \( \emptyset \), and let \( A_n \uparrow A \in \mathcal{C} \), \( B_n \downarrow B \in \mathcal{C} \). Then \( A - A_n \downarrow \emptyset \) \( \Rightarrow \varphi A - \varphi A_n \to 0 \) \( \Rightarrow \varphi A_n \to \varphi A \), and \( B_n - B \downarrow \emptyset \) \( \Rightarrow \varphi B_n - \varphi B \to 0 \) \( \Rightarrow \varphi B_n \to \varphi B \).

Note that part (b) is analogous to the fact that an additive transformation on a vector space is continuous iff it is continuous at the origin \( \theta \).

The following lemma depends strongly on the Continuity Theorem, and is in turn used to prove the Hahn-Jordan Theorem, which is used to prove the Radon-Nikodym Theorem.

**Maximum-minimum lemma.** Every real measure \( \varphi \) on a \( \sigma \)-field \( \mathcal{A} \) assumes a maximum and a minimum on \( \mathcal{A} \).

**Outline of Proof.** It suffices to assume that \( 0 < \sup \varphi \) and \( \varphi < \infty \); otherwise the proof is trivial. Choose \( A_n \in \mathcal{A} \) so that \( 0 < \varphi A_n \to \sup \varphi \), and let \( A = \bigcup A_n \). It follows by induction that for each \( n \), \( A \) can be partitioned into \( 2^n \) disjoint sets, say \( A = \bigcup_{m=1}^{2^n} A_{nm} \), where

\[
A_{nm} = \bigcap_{k=1}^n A_{nmk} \quad \text{and each } A_{nmk} \text{ is either } A_k \text{ or } A - A_k.
\]

Note that

\[
A_n = \sum[A_{nm} : A_{nmn} = A_n, \ 1 \leq m \leq 2^n].
\]

Let \( B_n = \sum[A_{nm} : \varphi A_{nm} > 0, \ 1 \leq m \leq 2^n] \). It follows that

\[
\varphi A_n \leq \varphi B_n \leq \varphi \bigcup_{k=n}^{n'} B_k \uparrow \varphi \bigcup_{k=n}^\infty B_k \text{ by continuity from below, then}
\]
sup $\phi \leq \phi \cap \bigcup_{n \geq k} B_k$, by continuity from above, since $\phi$ is finite.

Thus the maximum is attained, and similarly there is a set $D \in \mathcal{A}$ such that $-\phi D = \sup (-\phi)$, hence $\phi D = \inf \phi$.

**Hahn-Jordan Decomposition Theorem.** If $\phi$ is a real measure on a $\sigma$-field $\mathcal{A}$, then there is a set $D \in \mathcal{A}$ such that, for all $A \in \mathcal{A}$,

$$\phi(AD^c) = \sup_{A \supseteq B \in \mathcal{B}} \phi B \equiv \phi^+ A, \quad \phi(AD) = \inf_{A \supset B \in \mathcal{B}} \phi B \equiv -\phi^- A.$$ 

**Outline of Proof.** By the max-min lemma there is a set $D \in \mathcal{A}$ such that $\phi D = \inf \phi > -\infty$. Thus

$$\phi(D - AD) = \phi D - \phi AD \geq \phi D, \quad \phi(D + AD^c) = \phi D + \phi AD^c \geq \phi D$$

which implies $-\phi AD \geq 0$ and $\phi AD^c \geq 0$. Thus if $A \supset B$, then

$$\phi B \leq \phi BD^c \leq \phi BD^c + \phi AB^c D^c = \phi AD^c,$$

which means $\phi^+ A \leq \phi AD^c$, hence $\phi^+ A = \phi AD^c$. Similarly $\phi AD = -\phi^- A$, hence $\phi = \phi^+ - \phi^-$. 

Since $\phi^+$ and $\phi^-$ are measures, this means that every real measure is the difference of two measures. This result is analogous (and closely related) to the result that every function of bounded variation is the difference of two increasing functions.

The Borel $\sigma$-field $\mathcal{B}$ on the real line $\mathbb{R}$ is the minimal $\sigma$-field containing all open sets: $\mathcal{B} = \mathcal{U}$, where $\mathcal{U}$ is the usual topology on $\mathbb{R}$. Since every open set in $\mathbb{R}$ is a countable union of open intervals, it follows easily that $\mathcal{B}$ is the minimal $\sigma$-field containing the class $\mathcal{J}$ of
all open intervals. If \( \zeta = \{(a,b) : a, b \in \mathbb{R}\} \), \( \zeta_1 = \{(r,\infty) : r \in \mathbb{R}\} \), and \( \zeta_2 = \{(-\infty, r) : r \in \mathbb{R}\} \), then it follows easily that

\[
\mathcal{B} = \mathcal{U} = \mathcal{F} = \mathcal{B} = \mathcal{B}_1 = \mathcal{B}_2.
\]

Let \((\Omega, \mathcal{A}, \mu)\) be a measure space, and recall that a function \(X : \Omega \to \mathbb{R}\) is \((\mathcal{A}, \mathcal{B})\)-measurable if \(X^{-1} \mathcal{B} \subseteq \mathcal{A}\). Let \(\mathcal{M}\) denote the class of all \((\mathcal{A}, \mathcal{B})\)-measurable functions. Note that the class \(\mathcal{R}^\Omega\) of all functions \(X : \Omega \to \mathbb{R}\) is a \(\sigma\)-lattice, with \(X \leq Y\) iff \(X(\omega) \leq Y(\omega)\) for all \(\omega \in \Omega\). It will now be shown that \(\mathcal{M}\) is a sub-\(\sigma\)-lattice of \(\mathcal{R}^\Omega\).

Suppose \(\{X_n\} \subseteq \mathcal{M}\) and \(-\infty \leq \land X_n \leq \lor X_n \leq \infty\), and let \(X = \lor X_n = \sup X_n\). Then for each \(r \in \mathbb{R}\),

\[
X^{-1}(r, \infty) = \bigcup_k \{\omega : \sup_n X_n > r + \frac{1}{k}\} = \bigcup_m X_m^{-1}(r, \infty) \in \mathcal{A},
\]

since \(X_m \in \mathcal{M}\) for each \(m\), and this means \(X \in \mathcal{M}\) since \(\varnothing = \zeta_1\). Similarly it follows that \(\land X_n \in \mathcal{M}\), hence \(\limsup X_n = \land \lor X_k \in \mathcal{M}\) and \(\liminf X_n = \lor \land X_k \in \mathcal{M}\), which means that \(\lim X_n \in \mathcal{M}\) whenever it exists and is finite.

Functions of the form \(X = \sum_{j=1}^{m} x_j I_{A_j}\), where \(x_j \in \mathbb{R}\) and \(A_j \in \mathcal{A}\) for \(j = 1, \ldots, m\) are called (real) simple functions.

Suppose \(X \in \mathcal{M}\), and for each \(n = 1, 2, \ldots\), let

\[
X_n = \sum_{k=-n2^n}^{n2^n} \frac{k-1}{2^n} I_{\left[\frac{k-1}{2^n} \leq x < \frac{k}{2^n}\right]}
\]

Then clearly each \(X_n\) is a simple function, since \(X \in \mathcal{M}\) implies \(A_{nk} = X^{-1}\left[\frac{k-1}{2^n}, \frac{k}{2^n}\right] \in \mathcal{A}\). Furthermore, it is clear that
$X_n(\omega) \to X(\omega)$ for all $\omega \in \Omega$. In fact, if $X \geq 0$, then all terms for $k < 0$ vanish and $0 \leq X_n \uparrow X$. That is, every nonnegative measurable function is the limit of a nondecreasing sequence of nonnegative simple functions.

Two functions $X, Y \in \mathcal{M}$ are said to be equal almost surely (a.s.) (or almost everywhere), with respect to $\mu$, written $X \equiv_{a.s.} Y$, iff

$$\mu[ X \neq Y ] = 0.$$  It follows easily that $\equiv_{a.s.}$ is an equivalence relation, which therefore partitions $\mathcal{M}$ into equivalence sets. It will often be convenient to identify functions which are a.s. equal.

If $X : \Omega \to \mathbb{R}$ is the limit of a sequence of simple functions, then $X \in \mathcal{M}$, since the limit of a sequence of measurable functions is measurable. Therefore, $X \in \mathcal{M}$ if and only if there is a sequence of simple functions which converges to $X$. This implies at once that, if $X, Y \in \mathcal{M}$, then $aX$, $X + Y$, and $XY$ are also in $\mathcal{M}$. Thus $\mathcal{M}$ is a linear space, and also a ring (algebra).

Let $\mathcal{M}^+$ denote the class of all nonnegative measurable functions, and $\mathcal{M}_s^+$ the class of all nonnegative simple functions, and suppose $X, Y \in \mathcal{M}_s^+$, say

$$X = \sum_1^m x_j I_{A_j}, \quad Y = \sum_1^n y_k I_{B_k},$$

where $x_j, y_k \geq 0$, $A_j, B_k \in \mathcal{A}$, and $\Omega = \sum_1^m A_j = \sum_1^n B_k$. Then,

$$X = \sum_1^m \sum_1^n x_j I_{A_j B_k}, \quad Y = \sum_1^n \sum_1^m y_k I_{A_j B_k}.$$  

Note that if $X = Y$ and $A_j B_k \neq \emptyset$, then $x_j = y_k$, hence
\[ \sum_{j=1}^{m} x_j \mu A_j = \sum_{j=1}^{m} \sum_{k=1}^{n} x_j \mu A_j B_k = \sum_{k=1}^{n} \sum_{j=1}^{m} y_k \mu A_j B_k = \sum_{k=1}^{n} y_k \mu B_k. \]

**Definition.** \( \int X \, d\mu = \int X = \sum_{j=1}^{m} x_j \mu A_j \) if \( X = \sum_{j=1}^{m} x_j I A_j \in \mathcal{M}_s^+ \). It follows easily that, if \( X, Y \in \mathcal{M}_s^+ \), then \( \int aX = a \int X, \int (X+Y) = \int X + \int Y \), and \( X \leq Y \Rightarrow \int X \leq \int Y \). For the sake of convenience, \( \int X \, d\mu \) will usually be denoted by \( \int X \) whenever the measure \( \mu \) is understood.

The proof of the following lemma is again based on the Continuity Theorem, and justifies the crucial step in the definition of the integral.

**Monotone Convergence Lemma.** If \( X_n, Y \in \mathcal{M}_s^+ \) and \( X_n \uparrow X \geq Y \), then
\[
\lim \int X_n \geq \int Y.
\]

**Proof.** Consider first the case \( Y = IB \), where \( B \in \mathcal{A} \). Let \( \varepsilon > 0 \) and \( E_n = \{ \omega \in \omega : X_n(\omega) > 1 - \varepsilon \} \). Then \( E_n \uparrow B \), hence \( \mu E_n \uparrow \mu B \) by the Continuity Theorem. Thus \( \int X_n \geq \int \sum_{E_n} X_n \geq (1 - \varepsilon) \mu E_n \) implies
\[
\lim \int X_n \geq (1 - \varepsilon) \mu B,
\]
which implies \( \lim \int X_n \geq \mu B = \int Y \) since \( \varepsilon \) is arbitrary.

Now if \( Y = \sum_{k=1}^{m} y_k IB_k \), where \( \Omega = \sum_{k=1}^{m} B_k \), then \( \lim X_n \geq Y \) implies \( \lim X_n IB_k \geq y_k IB_k \) for \( k = 1, \ldots, m \), hence \( \lim \sum_{n} X_n IB_k \geq y_k \mu B_k \).

But \( \int X_n = \sum_{k=1}^{m} \int X_n IB_k \), hence
\[
\lim \int X_n = \sum_{k=1}^{m} \lim \int X_n IB_k \geq \sum_{k=1}^{m} y_k \mu B_k = \int Y.
\]

This implies that if \( X_n, Y_n \in \mathcal{M}_s^+ \) and \( X_n \uparrow X \), then
\[
\lim \int X_n = \lim \int Y_n. \quad \text{For } X_m \uparrow X \geq Y_n \text{ implies } \lim \int X_m \geq \int Y_n \text{ for all } n, \text{ hence } \lim \int X_m \geq \lim \int Y_n, \text{ and similarly the opposite inequality holds.}
\]

**Definition.** If \( X \in \mathcal{M}^+ \), then \( \int X = \lim \int X_n \), where \( X_n \in \mathcal{M}_s^+ \) and \( X_n \uparrow X \).

If \( X \in \mathcal{M} \), write \( X = X^+ - X^- \), where \( X^+ = \sup(X, 0) \) and \( X^- = -\inf(X, 0) \). If either \( \int X^+ < \infty \) or \( \int X^- < \infty \), define
\[
\int X = \int X^+ - \int X^-.
\]
Note that \( |\int X| \leq \int X^+ + \int X^- = \int (X^+ + X^-) = \int |X| \), and that \( |\int X| < \infty \) iff \( \int |X| < \infty \). The class of all \( X \in \mathcal{M} \) such that \( \int |X| < \infty \) will be denoted by \( \mathcal{L} \), and functions \( X \in \mathcal{L} \) will be called **Lebesgue summable**.

The following four theorems are among the most celebrated and powerful theorems in real analysis.

**Monotone Convergence Theorem.** If \( X_n \in \mathcal{M}^+ \) and \( X_n \uparrow X \), then \( \int X_n \uparrow \int X \).

**Proof.** For each \( n \), there is a sequence \( [X_{nk}] \) of simple functions such that \( 0 \leq X_{nk} \uparrow X_n (k \to \infty) \). Let \( Y_n = \sup [X_{mk} : 1 \leq m \leq n, 1 \leq k \leq n] \). Then \( Y_n \in \mathcal{M}_s^+ \) and \( X_n \geq Y_n \uparrow X \), therefore
\[
\lim \int X_n \geq \lim \int Y_n = \int X
\]
by the definition of \( \int X \). But clearly \( \lim \int X_n \leq \int X \), hence
\[
\lim \int X_n = \int X.
\]

The following famous lemma is a corollary of the Monotone
Convergence Theorem (MCT). The notation \( \lim = \lim \inf \) and \( \lim = \lim \sup \) will be used.

**Fatou's Lemma.** If \( X_n, Y \in \mathcal{M}^+ \) and \( \int Y < \infty \), then

(a) \( \lim \int X_n \geq \int \lim X_n \)

(b) \( \lim \int X_n \leq \int \lim X_n \) if \( X_n \leq Y \).

**Proof.** (a) Let \( X_n = \inf X_k \). Then \( X_n \uparrow X = \lim X_n \), hence

\[
\int X_n \geq \int X \uparrow \int X \quad \text{by the MCT, which implies that } \lim \int X_n \geq \int X.
\]

(b) Let \( \overline{X}_n = \sup X_k \). Then \( X_n \leq \overline{X}_n \downarrow \overline{X} = \lim X_n \), hence

\[
0 \leq \overline{X}_1 - \overline{X}_n \uparrow \overline{X}_1 - \overline{X}. \quad \text{This implies that } \int \overline{X}_1 - \int \overline{X}_n \uparrow \int \overline{X}_1 - \int \overline{X},
\]

hence \( \int X_n \leq \int \overline{X}_n \downarrow \int \overline{X} \), using the MCT and finiteness of the integrals.

Thus \( \lim \int X_n \leq \int \overline{X} \).

**Dominated Convergence Theorem (Lebesgue DCT).** If \( X_n \in \mathcal{M} \), \( |X_n| \leq Y \in \mathcal{A} \), and \( X_n \to X \), then \( X \in \mathcal{A} \) and \( \int X_n \to \int X \).

**Proof.** By hypothesis, \( X_n^+ \to X^+ \), \( X_n^- \to X^- \), and \( X_n^+ \), \( X_n^- \leq Y \). Therefore, by Fatou's lemma,

\[
\lim \int X_n^+ \leq \int X^+ \leq \lim \int X_n^+ < \infty \\
\lim \int X_n^- \leq \int X^- \leq \lim \int X_n^- < \infty.
\]

Thus \( \int X = \int X^+ - \int X^- \leq \lim \int X_n^+ - \lim \int X_n^- = \lim \int X_n^+ + \lim ( -\int X_n^-) \leq \lim (\int X_n^+ - \int X_n^-) = \lim \int X_n \). Similarly \( \lim \int X_n \leq \int X \), therefore
\[ \lim \int X_n = \int X. \]

The MCT and DCT remain valid if \( X_n \to X \) is replaced by \( X_n \xrightarrow{a.s.} X \); that is, \( \mu [X_n \leftrightarrow X] = 0. \)

If \( \mu \) is a measure and \( \varphi \) is a scalar measure, then \( \varphi \) is said to be \( \mu \)-continuous iff

\[ \mu A = 0 \implies \varphi A = 0. \]

**Radon-Nikodym Theorem.** Let \( \mu \) be a \( \sigma \)-finite measure on the \( \sigma \)-field \( \mathcal{A} \), and suppose \( \varphi : \mathcal{A} \to \mathbb{R} \) is a \( \sigma \)-finite scalar measure. Then \( \varphi \) is \( \mu \)-continuous iff there exists a function \( Y \in \mathcal{A} \), determined up to a \( \mu \) equivalence, such that

\[ \varphi A = \int_A Y \, d\mu, \quad A \in \mathcal{A}. \]

By definition, \( \frac{d\varphi}{d\mu} = Y. \)

The sufficiency follows from the MCT. For the proof of the necessity, see LOEVE.

Suppose now that \( X = X^r + iX^i : \Omega \to \mathbb{C}^r = \mathbb{C} \), where \( X^r, X^i \in \mathcal{M}_c \). The class of all such functions will be denoted by \( \mathcal{M}_c \). If \( X^r, X^i \in \mathcal{L}_c \), then by definition \( \int X = \int X^r + i\int X^i \), and the class of all these functions is denoted by \( \mathcal{L}_c \). It follows easily that \( \mathcal{M}_c \) and \( \mathcal{L}_c \) are linear spaces, and \( \mathcal{L}_c \) is a NLS with norm defined by

\[ \|X\| = \int |X|. \]

Writing \( \int X = \int |X| e^{i\alpha} \), it follows that \( \int |X| = \int X e^{-i\alpha} \leq \int |X| \).
The Dominated Convergence Theorem extends immediately to the case of complex valued functions, for if \( |X_n| \leq Y \in \mathcal{X} \), then \( |X_n^+|, |X_n^-| \leq Y \); so that \( X_n \to X \) implies \( \lim \int X_n^+ = \int X^+ \) and \( \lim \int X_n^- = \int X^- \).

If \( X \in \mathcal{M}^+ \) and \( \int X = 0 \), then \( X \overset{a.s.}{=} 0 \). That is, \( \mu[X > 0] = 0 \), or equivalently \( \mu[X > \frac{1}{n}] = 0 \) for every \( n \) by the Continuity Theorem, since

\[
[x > \frac{1}{n}] \uparrow [x > 0].
\]

For if \( \mu[X > \frac{1}{n}] = a_n > 0 \) for some \( n \), then

\[
\int X \geq \int X \geq \frac{1}{n} \mu[X > \frac{1}{n}] = \frac{1}{n} a_n ,
\]

which is a contradiction.

Thus if \( X \in \mathcal{X} \) and \( \int_A X = 0 \) for every \( A \in \mathcal{A} \), then

\[
\int X = 0 \text{ implies } X^+ \overset{a.s.}{=} 0 , \text{ and } [x \geq 0] \\
\int X = 0 \text{ implies } X^- \overset{a.s.}{=} 0 , \text{ and } [x \leq 0]
\]

hence \( X = X^+ - X^- \overset{a.s.}{=} 0 \). These simple facts are often useful.

**Schwarz Inequality.** If \( |X|^2, |Y|^2 \in \mathcal{X} \), then

\[
\left( \int |XY| \right)^2 \leq \left( \int |X|^2 \right) \left( \int |Y|^2 \right).
\]

**Proof.** \( \int \left( |X| + \lambda |Y| \right)^2 = \int |X|^2 + 2\lambda \int |XY| + \lambda^2 \int |Y|^2 \geq 0 \) for all \( \lambda \in \mathbb{R} \). \( \square \)
Markov-Tchebychev Inequality. If $X \in \mathcal{M}$, $r \in \mathbb{R}$ and $\varepsilon > 0$, then

$$\mu[|X| \geq \varepsilon] \leq \varepsilon^{-r} \int |X|^r$$

Proof. $\int |X|^r \geq \int |X|^r \mathbf{1}_{|X| \geq \varepsilon} \geq \varepsilon^{-r} \mu[|X| \geq \varepsilon]$.

The expectation of a vector valued random variable is defined as its Bochner integral. Before defining the Bochner integral, however, the following convergence theorems are needed. Let $(\Omega, \mathcal{A}, \mu)$ be a measure space and $X_n, X : \Omega \to \mathbb{X}$. Then

(a) $X_n \xrightarrow{a.s.} X$ iff there exists a null set $N$ such that

$$X_n \to X \text{ on } N^c,$$

(b) $X_n \xrightarrow{a.s.u.} X$ (almost uniformly) iff for every $\varepsilon > 0$ there is a set $A_\varepsilon \in \mathcal{A}$ such that $\mu A_\varepsilon < \varepsilon$ and

$$X_n \xrightarrow{u} X \text{ (uniformly) on } A_\varepsilon^c,$$

(c) $X_n \xrightarrow{\mu} X$ iff for every $\varepsilon > 0$

$$\mu[\omega : |X_n(\omega) - X(\omega)| \geq \varepsilon] \to 0.$$

Convergence Theorem. Let $X_n, X : \Omega \to \mathbb{X}$ be functions such that $|X_m - X|, |X_m - X_n| \in \mathcal{M}$.

(a) $\mu$ finite $\Rightarrow X_n \xrightarrow{a.s.} X$ iff $\lim \mu \bigcup_{m \geq n} [X_m - X] \geq \varepsilon] = 0$ for every $\varepsilon > 0$,

(b) $X_m - X_n \xrightarrow{a.s.} 0$ iff $\mu \bigcap_{m \geq n} \bigcup \ [X_m - X_n] \geq \varepsilon] = 0$ for every $\varepsilon > 0$,

(c) if $X_m - X_n \xrightarrow{\mu} 0$, then there is a subsequence, say $X_{n'}$,
such that \( X_m - X_n \xrightarrow{a.s.} 0 \).

**Proof.** By definition, \( X_n \xrightarrow{a.s.} X \) iff \( \mu[X_n \not\xrightarrow{} X] = 0 \). But

\[
[X_n \xrightarrow{} X] = \bigcap_k \left[ \text{for some } n, \ |X_m - X| < \frac{1}{k} \text{ for all } m \geq n \right]
\]

\[
= \bigcap_k \bigcup_n \bigcap_{m \geq n} \left[ |X_m - X| < \frac{1}{k} \right].
\]

Therefore, by DeMorgan's laws,

\[
[X_n \not\xrightarrow{} X] = \bigcup_k \bigcap_n \bigcup_{m \geq n} \left[ |X_m - X| \geq \frac{1}{k} \right].
\]

By the Continuity Theorem it follows that

\[
\mu[X_n \not\xrightarrow{} X] = \lim_{k} \mu \bigcap_n \bigcup_{m \geq n} \left[ |X_m - X| \geq \frac{1}{k} \right] = 0 \text{ iff }
\]

\[
\mu \bigcap_n \bigcup_{m \geq n} \left[ |X_m - X| \geq \frac{1}{k} \right] = 0 \text{ for every } k.
\]

But applying the Continuity Theorem again, the above is equal to

\[
\lim_{n} \mu \bigcup_{m \geq n} \left[ |X_m - X_n| \geq \frac{1}{k} \right], \text{ and (a) follows.}
\]

The proof of (b) is similar to the first part of (a).

Now suppose \( X_j - X_k \xrightarrow{P} 0 \), so that \( \mu[|X_j - X_k| \geq 2^{-n}] \rightarrow 0 \) \((j, k, \rightarrow \infty)\) for each \( n \). Choose \( q_n \) so that \( q_n \uparrow \infty \) and

\[
j, k \geq q_n \Rightarrow \mu[|X_j - X_k| \geq 2^{-n}] < 2^{-n}
\]

and let \( Y_n = X_{q_n} \).

Given \( \epsilon > 0 \), consider \( n \) sufficiently large so that \( 2^{-n+1} < \epsilon \).

It follows that
\[ \bigcap_{m \geq n} [Y_{m+1} - Y_m < 2^{-m}] \subset \bigcap_{m \geq n} [Y_m - Y_n < \varepsilon] \]

since \( |Y_m - Y_n| \leq \sum_{m \geq n} |Y_{m+1} - Y_m| \) for \( m \geq n \).

Thus \( \mu \bigcap_{n} \bigcup_{m \geq n} [|Y_m - Y_n| \geq \varepsilon] \leq \mu \bigcup_{m \geq n} [|Y_m - Y_n| \geq \varepsilon] \leq \mu \bigcup_{m \geq n} [|Y_{m+1} - Y_m| \geq 2^{-m}] \leq \sum_{m \geq n} \mu [|Y_{m+1} - Y_m| \geq 2^{-m}] \leq \sum_{m \geq n} 2^{-m} = 2^{-n+1} \rightarrow 0 \)

Therefore \( Y_m - Y_n \overset{a.s.}{\longrightarrow} 0 \) by part (b).

**Egorov's Theorem.** If \( \mu \) is finite, then \( X_n \overset{a.s.}{\longrightarrow} X \).

**Proof.** If \( m \) is any positive integer, then \( \lim_{n \to \infty} \mu \bigcup_{k=n}^{\infty} (|X_k - X| \geq \frac{1}{m}) = 0 \) by the convergence a.e. criterion (a). Therefore, given \( \varepsilon > 0 \), \( n(m) \) can be chosen so that \( \mu A_m = \mu \bigcup_{k=n(m)}^{\infty} (|X_k - X| \geq \frac{1}{m}) < \frac{\varepsilon}{2^n} \), for \( m = 1, 2, \ldots \).

Let \( A = \bigcup A_m^c \). Then \( \mu A \leq \sum \mu A_m < \sum \frac{\varepsilon}{2^m} = \varepsilon \). But

\[ A^c = \bigcap A_m^c = \bigcap_{m=1}^{\infty} \bigcap_{k=n(m)}^{\infty} (|X_k - X| < \frac{1}{m}) \]

thus if \( \omega \in A^c \) then, for \( k \geq n(m) \), \( |X_k(\omega) - X(\omega)| < \frac{1}{m} \) unif. on \( A^c \)

A measure \( \mu \) is \( \sigma \)-finite iff there exist sets \( A_n \in \mathcal{A} \) such that \( \mu A_n < \infty \) and \( \Omega = \Sigma A_n \).

**Lusin's Theorem.** If \( \mu \) is \( \sigma \)-finite and \( X_n \overset{a.s.}{\longrightarrow} X \), then there is a
\(\mu\)-null set \(N\) and a countable partition \(N^C = \sum A_j\), where each \(A_j \in \mathcal{A}\), and \(\mu A_j < \infty\), such that \(X_n \stackrel{\text{u}}{\rightarrow} X\) on \(A_j\) for each fixed \(j\).

**Proof.** Since \(\mu\) is \(\sigma\)-finite, it suffices to assume that \(\mu\) is finite.

Using Egorov’s Theorem, select \(A_1\) so that \(\mu A_1 < 1\) and \(X_n \stackrel{\text{u}}{\rightarrow} X\) on \(A_1^c\). For \(n = 2\), select \(A_2\) so that \(\mu A_1 A_2 < \frac{1}{2}\) and \(X_n \stackrel{\text{u}}{\rightarrow} X\) on \(A_2^c\).

In general, select \(A_n\) so that \(\mu \bigcap_{k=1}^{n} A_k < \mu A_n < \frac{1}{n}\) and \(X_n \stackrel{\text{u}}{\rightarrow} X\) on \(A_n^c\).

By the Continuity Theorem, \(\mu \bigcap_{k=1}^{\infty} A_k = \lim_{k \to \infty} \mu \bigcap_{k=1}^{n} A_k = 0\). Let \(A = \bigcap_{k=1}^{\infty} A_k^c\), which can be written as a countable sum of sets, on each of which \(X_n \stackrel{\text{u}}{\rightarrow} X\). Thus the theorem is true with \(A = N\).

**Diagonal Convergence Theorem.**

(a) If \(\mu\) is finite, \(X_{mn} \xrightarrow{a.s.} X_m (n \to \infty)\), and \(X_m \xrightarrow{a.s.} X\), then there exist sequences \(m_k, n_k\) of positive integers such that \(X_{m_k,n_k} \xrightarrow{a.s.} X (k \to \infty)\).

(b) If \(\mu\) is \(\sigma\)-finite, say \(\Omega = \sum A_j\) where \(\mu A_j < \infty\) for each \(j\), \(X_{mn} \xrightarrow{a.s.} X_m (n \to \infty)\), and \(X_m \xrightarrow{a.s.} X\), then for each \(j\) there exist sequences \(m(j,k), n(j,k)\) of positive integers such that \(X_{m(j,k),n(j,k)} \xrightarrow{a.s.} X (k \to \infty)\) on \(A_j\), thus

\[X'_k = \sum_{j=1}^{k} IA_j X_{m(j,k),n(j,k)} \xrightarrow{a.s.} X (k \to \infty)\) on \(\Omega\).

If the \(X_{mn}\) are simple functions, then so are the \(X'_k\).

**Proof.** Since \(X_m \xrightarrow{a.s.} X\), for each \(k = 1, 2, \ldots\) there is a set \(A_k \in \mathcal{A}\) such that \(\mu A_k < 2^{-k}\) and \(X_m \stackrel{\text{u}}{\rightarrow} X\) on \(A_k^c\), using Egorov's theorem.

Choose \(m_k\) so that \(|X_{m_k} - X| < 2^{-k}\) uniformly on \(A_k^c\). Now for each
Therefore, again by Egoroff's theorem, there is a set $B_k \subseteq A_k^c$ such that $\mu B_k < 2^{-k}$, and then $n_k$ can be chosen so that $
abla \mu_{m_kn_k} - \mu_{m_k} < 2^{-k}$ uniformly on $A_k^c B_k^c$.

Let

$$A = \bigcap_{k=1}^{\infty} \bigcup_{j=k}^{\infty} A_{k,j}^c$$
$$B = \bigcap_{i=1}^{\infty} \bigcup_{j=i}^{\infty} B_{j}.$$

Then $\mu A = \lim_{k \to \infty} \mu \bigcup_{j=k}^{\infty} A_j \leq \lim_{k \to \infty} \sum_{j=k}^{\infty} 2^{-j} = 0$, and similarly $\mu B = 0$.

$$A^c = \bigcup_{k=1}^{\infty} \bigcap_{j=k}^{\infty} A_{k,j}^c, B^c = \bigcup_{i=1}^{\infty} \bigcap_{j=i}^{\infty} B_{j}^c.$$

Let $N = A \cup B$, so that

$$N^c = A^c B^c = \bigcup_{k=1}^{\infty} \bigcap_{i=1}^{\infty} \bigcup_{j=k}^{\infty} A_{k,i}^c B_{j}^c.$$

Thus if $\omega \in N^c$, then for some $q$, $\omega \in A_{k}^c B_{k}^c$ for all $k \geq q$.

$$|X_{m_k n_k}(\omega) - X(\omega)| \leq |X_{m_k n_k}(\omega) - X_{m_k}(\omega)| + |X_{m_k}(\omega) - X(\omega)|$$

$$< 2^{-k} + 2^{-k} = 2^{-k+1}$$

for all $k \geq q$, which means that $X_{m_k n_k} \to X$ on $N^c$. Part (b) follows directly from (a), using $\sigma$-finiteness.

Let $X$ be a Banach space with norm topology $\mathcal{U}$ and Borel $\sigma$-field $\mathcal{B} = \overline{\mathcal{U}}$, and suppose $\mu$ is a $\sigma$-finite measure on $\mathcal{A}$.

A simple function means a function of the form $X = \sum_{1}^{m} x_j I_{A_j}$,
where \( A_j \in \mathcal{A} \) and \( \mu A_j < \infty \). The class of all simple functions is again denoted by \( m_s \), and the integral is defined by \( \int X = \sum_{j=1}^{m} x_j \mu A_j \), exactly as in the scalar case.

A function \( X: \Omega \to X \) is said to be

1. \( (\mathcal{A}, \mathcal{B}) \)-measurable iff \( X^{-1} \mathcal{B} \subseteq \mathcal{A} \),
2. strongly measurable iff there exists a sequence of simple functions \( X_n \) such that \( X_n \stackrel{a.s.}{\to} X \),
3. weakly measurable iff \( fX : \Omega \to Z \) is a measurable scalar function for every continuous linear functional \( f : X \to Z \).

These classes of functions will be denoted by \( \mathcal{M}(\mathcal{A}, \mathcal{B}), \mathcal{M}, \) and \( \mathcal{M}_w \) respectively; if \( X = Z \), then they are clearly identical. It follows immediately that \( \mathcal{M} \) and \( \mathcal{M}_w \) are linear spaces, but \( \mathcal{M}(\mathcal{A}, \mathcal{B}) \) is not necessarily a linear space unless \( X \) is separable. In fact NEDOMA has given a counterexample in case the cardinal number of \( X \) is greater than the power of the continuum.

If \( X \in \mathcal{M} \) and \( g : X \to Z \) is continuous, it follows immediately that \( gX \) is a measurable scalar function, since any function of a simple function is simple. Therefore in particular \( \mathcal{M} \subseteq \mathcal{M}_w \).

If \( X_n \in \mathcal{M} \) and \( X_n \stackrel{a.s.}{\to} X \), then it follows from the Diagonal Convergence Theorem that \( X \in \mathcal{M} \), since \( \mu \) is \( \sigma \)-finite. If \( X_n \in \mathcal{M}_w \) and \( X_n \stackrel{a.s.}{\to} X \), then it follows immediately that \( X \in \mathcal{M}_w \), since the class of all measurable scalar functions is closed under limits.

**Measurable Functions Theorem.** If \( X \) is separable, then every \( (\mathcal{A}, \mathcal{B}) \)-measurable function \( X : \Omega \to X \) is strongly measurable, thus

\[
\mathcal{M}(\mathcal{A}, \mathcal{B}) \subseteq \mathcal{M} \subseteq \mathcal{M}_w.
\]
Proof. Let \([v_n]\) be a countable dense set, \(\varepsilon > 0\), and \(S_n = S(x_n, \varepsilon)\). Then \(X = \bigcup S_n = \sum B_n\), where \(B_n = S_n \cdot \bigcap_{k=1}^{n-1} S_k \in \mathcal{G}\) hence
\[\Omega = \sum X^{-1}B_n = \sum A_n,\] where \(A_n = X^{-1}B_n \in \mathcal{G}\) since \(X \in \mathcal{M}(\mathcal{A}, \mathcal{G})\).

Define \(X_\varepsilon(\omega) = \sum v_n I_{A_n}(\omega)\), and let any \(\omega \in \Omega\) be given, say \(\omega \in A_n = X^{-1}B_n\). Then \(X(\omega) \in B_n \subset S_n\), hence \(|X_\varepsilon(\omega) - X(\omega)| = |v_n - X(\omega)| < \varepsilon\).

This implies that there exists a sequence \(X_n\) of elementary functions such that \(X_n \to X\) everywhere. Since \(\mu\) is \(\sigma\)-finite, it now follows from the Diagonal Convergence Theorem that there is a sequence \(X'_n\) of simple functions such that \(X'_n \to X\).

If \(X\) is weakly measurable and \(\mathcal{J}\) is the usual topology on \(Z\), then \((fX)^{-1}\mathcal{J} = X^{-1}(f^{-1}\mathcal{J}) \subset \mathcal{A}\) for every continuous linear functional \(f : X \to Z\) and \(\mathcal{J} = \bigcup f^{-1}\mathcal{J} \subset \mathcal{U}\) since each \(f\) is continuous. In the next chapter it will be shown, with the aid of the Hahn-Banach Theorem, that \(\mathcal{U} = \mathcal{J}\) whenever \(X\) is separable. But recall that \(X^{-1}\mathcal{J} \subset \mathcal{A}\) implies \(X^{-1}\mathcal{J} \subset \mathcal{A}\). Therefore every weakly measurable function is \((\mathcal{A}, \mathcal{B})\)-measurable in case \(X\) is separable, which means that all three notions of measurability are the same.

A function \(X : \Omega \to X\) is said to be a.s. separably valued iff there exists a \(\mu\)-null set \(N\) such that \(X[N^c]\) is separable. It is a rather remarkable fact, proved by Pettis, that every strongly measurable function is a.s. separably valued. Because of this and other considerations, including the example of Nedoma mentioned above, \(X\) is usually assumed to be separable.

It is easily seen that \(|\int X| \leq \int |X|\) for any \(X \in \mathcal{M}_s\). A norm is defined on the linear space \(\mathcal{M}_s\) by writing
\[ \|X\| = \int |X| = \int |x| \, d\mu. \]

The Bochner integral of a strongly measurable function is then defined by completing the normed linear subspace \( M_s \) with respect to this norm, using the Cantor completion method.

**Definition.** A function \( X \in M \) is **Bochner summable** iff there exists a sequence \( X_n \in M_s \) such that \( X_n \overset{a.s.}{\to} X \) and

\[ \|X_n - X\| = \int |X_n - X| \to 0. \]

It follows that \( \int X_n \) is a Cauchy sequence, and by definition

\[ \int X = \lim \int X_n. \]

If \( Y_n \in M_s \) is another such sequence, then

\[ \left| \int X_m - \int Y_n \right| \leq \int |X_m - X| + \int |Y_n - X| \]

implies that \( \lim \int X_m = \lim \int Y_n \), so \( \int X \) is well defined. Since every Cauchy sequence is bounded, it follows easily that \( |\int X| \leq \int |X| = \|X\| < \infty. \)

This method is due to DUNFORD [1]. Actually he starts out slightly further down the line, with Cauchy sequences in \( M_s \). But it is not difficult to show, using the Markov inequality

\[ \left[ |X_m - X_n| \geq \varepsilon \right] \leq \frac{1}{\varepsilon} \|X_m - X_n\| \]

and the Convergences Theorem, that every Cauchy sequence \( X_n \in M_s \) has a subsequence \( X_n \overset{a.s.}{\to} X \in M \).

The class of all Bochner summable functions will be denoted by \( \mathcal{L} \), just as in the scalar case. It follows directly from the definition
that $\mathcal{A}$ is a NLS with norm $\|X\| = \int |X|$. In case $X = \mathbb{Z}$, it is obvious from the definitions that a function $X : \Omega \to \mathbb{Z}$ is Bochner summable iff it is Lebesgue summable in the old sense, so that the definition of the Bochner integral is consistent.

A function $X : \Omega \to \mathbb{Z}$ is said to be square summable iff there is a sequence $X_n \in \mathcal{M}$ such that $X_n \overset{\text{a.s.}}{\to} X$ and

$$\|X_n - X\|_2^2 = \int |X_n - X|^2 \to 0.$$

It follows from the Schwarz inequality (for real functions) that

$$\|X + Y\|_2 \leq \|X\|_2 + \|Y\|_2,$$

whence $\|X_n + Y_n - X - Y\|_2 \leq \|X_n - X\|_2 + \|Y_n - Y\|_2$. Therefore the class $\mathcal{A}^2$ of square summable functions is a NLS with

$$\|X\|_2^2 = \int |X|^2 < \infty.$$

Notice that a square summable function is not necessarily summable. But it follows from the Schwarz inequality that for any subset $A \in \mathcal{A}$ such that $\mu A < \infty$,

$$\int_A |X_n - X| \leq (\mu A) \left( \int_A |X_n - X|^2 \right)^{1/2}.$$

Hence every square summable function is summable over sets of finite measure. In particular, $\mathcal{A}^2 \subset \mathcal{A}$ if $\mu$ is finite.

**Riesz-Fischer Theorem.** The space $\mathcal{A}^r$ ($r = 1, 2$) is equal to 

$[X \in \mathcal{M} : \int |X|^r = \|X\|^r < \infty]$, and is a Banach space if functions are identified with their $\mathcal{M}$-equivalence sets.

**Proof.** It has already been noted that $X \in \mathcal{A}^r$ implies $\int |X|^r < \infty$, and that $\mathcal{A}^r$ is a NLS with norm defined by $\|X\| = \left(\int |X|^r\right)^{1/r}$. Clearly
\[ \|X\| = 0 \text{ implies } X \stackrel{s.a.}{\to} 0. \]

Now suppose \( X \in \mathcal{M}, \int |X|^\tau < \infty \), and choose \( X_n \in \mathcal{M}_s \) so that \( X_n \overset{a.s.}{\to} X \). Since \( \mu \) is \( \sigma \)-finite, by Lusin's Theorem there is a null set \( N \) and a countable partition \( N^c = \Sigma A_k \) such that \( A_k \in \cap \), \( 0 < \mu A_k < \infty \), and \( X_n \overset{u}{\to} X \) on \( A_k \) for each \( k = 1, 2, \ldots \). Let \( \varepsilon > 0 \) be given, and for each \( k \) choose \( n_k \) so that \( |X_{n_k} - X|^\tau < \frac{\varepsilon}{2^k \mu A_k} \) uniformly on \( A_k \); then define \( X_\varepsilon = \sum X_{n_k} I_{A_k} \) and \( X_{\varepsilon m} = \sum_{k=1}^m X_{n_k} I_{A_k} \).

It follows by the Monotone Convergence Theorem that
\[ \int |X_\varepsilon - X|^\tau = \sum \int_{A_k} |X_\varepsilon - X|^\tau \leq \sum \frac{\varepsilon}{2^k} = \varepsilon \]
and
\[ \int |X_\varepsilon|^\tau = \sum \int_{A_k} |X_{n_k}|^\tau \leq 2 \int |X_\varepsilon - X|^\tau + 2 \int |X|^\tau < \infty, \]
hence
\[ \int |X_\varepsilon - X_{\varepsilon m}|^\tau = \sum \int_{A_k} |X_{n_k}|^\tau \to 0 \text{ as } m \to \infty. \]

Note that \( X_\varepsilon \) is an elementary function and \( X_{\varepsilon m} \) is a simple function for each \( m \), since \( \mu A_k < \infty \). If \( m \) is now chosen so that \( \int |X_\varepsilon - X_{\varepsilon m}| < \varepsilon \), then
\[ \int |X - X_{\varepsilon m}|^\tau \leq 2 \int |X - X_\varepsilon|^\tau + 2 \int |X_\varepsilon - X_{\varepsilon m}|^\tau < 4\varepsilon. \]

Thus if \( X \in \mathcal{M} \) and \( \int |X|^\tau < \infty \), then there is a sequence \( X'_n \in \mathcal{M}_s \) such that \( \int |X'_n - X|^\tau = \|X'_n - X\|^2 \to 0. \) But this implies that
for every \( \varepsilon > 0 \) by the Markov-Tchebychev inequality. It then follows from the Convergences theorem that there is a subsequence \( X^n \) such that
\[ X^n \xrightarrow{a.s.} X ; \]
and clearly \( \int |X^n - X|^r \to 0 \). Therefore
\[ r^X = \{ X \in \mathcal{M} : \int |X|^r < \infty \} \] .

Now suppose \( X_n \) is a Cauchy sequence in \( r^X \). Then
\[ \mu( |X_m - X_n| \geq \varepsilon ) \leq \varepsilon^{-r} \|X_m - X_n\|^r \to 0 \]
for every \( \varepsilon > 0 \) by the Markov-Tchebychev inequality, so by the Convergences Theorem there is a subsequence \( Y_n \) such that \( Y_m - Y_n \xrightarrow{a.s.} 0 \). Since \( X \) is complete, \( Y_n \xrightarrow{a.s.} Y \); and \( Y \in \mathcal{M} \) since \( \mathcal{M} \) is closed under a.s. limits.

Now \( X_m - Y_n \xrightarrow{a.s.} X_m - Y \) (n \( \to \infty \)) for each \( m \), so by Fatou's lemma it follows that
\[ \int |X_m - Y|^r = \int \lim_n |X_m - Y_n|^r \leq \lim_n \int |X_m - Y_n|^r \to 0 \quad (m \to \infty) \]
and \( \int |Y|^r \leq \lim_n \int |Y_n|^r < \infty \) since every Cauchy sequence is bounded.

This means \( r^X \) is complete, hence is a Banach space, which completes the proof.

Dominated Convergence Theorem. If \( X_n \in \mathcal{A} \), \( X_n \xrightarrow{a.s.} X \), and \( |X_n| \leq g \in \mathcal{A}_{\text{Real}} \), then \( X \in \mathcal{A} \) and \( \int X_n \to \int X \).

Proof. Clearly \( |X| = \lim |X_n| \leq g \) a.s.; hence \( \int |X| < \infty \) and the previous theorem implies \( X \in \mathcal{A} \). Furthermore \( |X_n - X| \to 0 \), \( |X_n - X| \leq 2g \).
implies $\int |X_n - X| \to 0$ by the Lebesgue DCT, and

$$|\int X_n - \int X| \leq \int |X_n - X| \to 0 \quad \Rightarrow \quad \int X_n \to \int X.$$  

**Hilbert Space.** Now consider the space $\mathbb{R}^2$ in the case $X = \mathbb{Z}$. Note that $x, y \in \mathbb{R}^2$ implies $xy^* \in \mathbb{R}^2$ by the Schwarz inequality. Define $x^* y = \int xy$, called the inner product (dot product) of $x$ and $y$, and note that $\|x\|^2 = x^* x$. The space $\mathbb{R}^2$ is an important example of a Hilbert space. Since Hilbert spaces occur frequently and have many of the properties of Euclidean space that Banach spaces do not have in general, it is appropriate to develop some of their basic properties here. For a more complete discussion see AKHIESER and GLAZMAN, HALMOS [2], KOLMOGOROV and FOMIN, RIESZ and SZ. NAGY, SIMMONS, or VON NEUMANN.

Let $X$ be a linear space. An inner product on $X$ is a scalar valued function $\cdot$ on $X \times Y$, with $(x, y)$ denoted by $x \cdot y$, such that

1. $(x + y) \cdot z = x \cdot z + y \cdot z$
2. $(\alpha x) \cdot y = \alpha (x \cdot y)$
3. $x \cdot y = (y \cdot x)^*$
4. $x \cdot x > 0$ if $x \neq 0$

An inner product space (IPS) is a pair $(X, \cdot)$ consisting of a linear space and an inner product on it. It follows that $\theta \cdot y = x \cdot \theta = 0$, $x \cdot (y + z) = x \cdot y + x \cdot z$, and $x \cdot (\alpha y) = \alpha (x \cdot y)$. Two vectors $x, y$ are said to be orthogonal, written $x \perp y$, iff $x \cdot y = 0$. If $M \subseteq X$, then $x \perp M$ means $x \perp y$ for all $y \in M$, and $M^\perp = \{x : x \perp M\}$.

By definition $|x| = (x \cdot x)^{1/2}$, and it follows that $|\alpha x| = |\alpha||x|$, $|x| = 0 \Rightarrow x = \theta$, and
\[ |x + y|^2 = |x|^2 + 2\text{Re}(x \cdot y) + |y|^2 \leq |x|^2 + 2|x|y + |y|^2. \]

Thus the triangle inequality follows from

\[ |x \cdot y| \leq |x||y| \quad \text{(Schwarz Inequality)}. \]

If \( u \) and \( v \) are unit vectors such that \( u \cdot v > 0 \), then the Schwarz inequality follows immediately from \( |u - v|^2 = 2 - 2|u \cdot v| \geq 0 \), and it is trivially true for \( x \perp y \). Otherwise let \( u = (e^{-i\alpha}) \frac{x}{|x|} \) and \( v = \frac{y}{|y|} \), where \( \alpha = \arg x \cdot y \). The equality sign holds in the Schwarz inequality if and only if \( x \) and \( y \) are proportional; hence the equality sign holds in the triangle inequality if and only if \( x \) and \( y \) are proportional with positive proportionality constant. A Hilbert space is an IPS which is also a Banach space with respect to the norm defined by \( |x|^2 = x \cdot x \).

It follows by expansion that \( \left| \sum_{1}^{n} x_j \right|^2 = \sum_{1}^{n} \sum_{1}^{n} x_j \cdot x_k \). Hence if the vectors \( x_j \) are orthogonal, then

\[ \left| \sum_{1}^{n} x_j \right|^2 = \sum_{1}^{n} |x_j|^2 \quad \text{(Pythagorean Law)}. \]

A sequence \([y_n]\) is orthonormal iff \( y_j \cdot y_k = \delta_{jk} \). Suppose \([y_n]\) is an orthonormal sequence, and let \( x \) be an arbitrary vector. If

\[ x_n = \sum_{1}^{n} (x \cdot y_k)y_k \]

then

\[ x \cdot x_n = x_n \cdot x_n = |x_n|^2 = \sum_{1}^{n} |x \cdot y_k|^2, \]

hence \( x - x_n \) \cdot \( x_n = 0 \) and
\[ |x|^2 = |x - x_n|^2 + |x_n|^2 \geq \sum_{k=1}^{n} |x - y_k|^2 \]

by the Pythagorean Law. It follows that

\[ \sum |x \cdot y_n|^2 \leq |x|^2 \quad \text{(Bessel's Inequality)} \]

which implies that \( \sum (x \cdot y_n) y_n \) always converges, since the partial sums are a Cauchy sequence and \( X \) is complete. But clearly \( x_n \to x \) if and only if \( |x_n|^2 \to |x|^2 \), so the equality sign holds in Bessel's inequality if and only if \( \sum (x \cdot y_n)y_n = x \).

If \( X \) is a Hilbert space, then a set \( \{y_i : i \in I\} \) of distinct orthonormal vectors in \( X \) is called a basis for \( X \) iff it is a maximal set in the class \( \mathcal{B} \) of all orthonormal sets:

\[ \{y_i : i \in I\} \subset \{z_j : j \in J\} \quad \Rightarrow \quad \{y_i : i \in I\} \neq \{z_j : j \in J\} \]

It follows that \( \{y_i : i \in I\} \) is a basis for \( X \) if and only if \( x \cdot y_i \) for all \( i \in I \) implies \( x = 0 \).

Assume \( X \neq \{0\} \). Then \( \mathcal{B} \) is nonempty and partially ordered by inclusion, and every chain \( \zeta \subset \mathcal{B} \) is easily seen to have an upper bound, namely \( \bigcup \zeta \). Therefore, by Zorn's lemma, there always exists a basis.

If \( X \) is separable, then every basis for \( X \) is countable. For suppose \( \{x_n\} \) is a countable dense set, and let \( \{y_i\} \) be a basis. If \( i \neq j \), then \( |y_i - y_j|^2 = |y_i|^2 + |y_j|^2 = 2 \). Thus if \( \{y_i\} \) is uncountable, then every dense set must be uncountable since the spheres \( S(y_i, 1) \) are disjoint.

**Basis Theorem.** A countable orthonormal set \( \{y_n\} \) is a basis for \( X \) iff \( x = \sum (x \cdot y_n)y_n \) for all \( x \in X \).
Proof. By Bessel's inequality it follows that $\sum (x \cdot y_n) y_n$ converges to some vector, say $y$. But $y \cdot y_m = x \cdot x_m \geq (y - x) \cdot y_m \geq y = x$, by completeness.

Conversely, if $\sum (x \cdot y_n) y_n = x$ for all $x$, then $(x \cdot y_n) = 0$ for all $n$ obviously implies $x = 0$.

In particular, if $[y_n]$ is a countable basis, then $X$ is necessarily separable, since the set $[z_n]$ of all finite linear combinations of the vectors $y_n$, with rational coefficients, is dense in $X$. Thus $X$ is separable if and only if it has a countable basis.

It follows by expansion that

$$|x + y|^2 + |x - y|^2 = 2|x|^2 + 2|y|^2 \text{ (Parallelogram Law)}$$

and $4(x \cdot y) = |x + y|^2 - |x - y|^2 + i|x + iy|^2 - i|x - iy|^2$.

The parallelogram law is characteristic of Hilbert space. In fact, VON NEUMANN showed that if $X$ is a NLS satisfying the parallelogram law, then the above expression defines an inner product.

A subset $M$ of a linear space is a manifold iff $x, y \in M$ implies $ax + by \in M$. The following theorem shows that Hilbert space has one of the most important properties of Euclidean space.

**Perpendicular Distance Theorem.** If $M$ is a subspace (closed manifold) of a Hilbert space $X$ and $x \in X$, then there is a unique vector $x_0 \in M$ such that $|x - x_0| = \inf \{|x - y| : y \in M\} = d$. Furthermore $x - x_0 = z \perp M$.

**Proof.** Choose $[x_n] \subseteq M$ so that $|x - x_n| \to d$, and note that by the Parallelogram Law,
\[
\begin{align*}
|(x - x_m) + (x - x_n)|^2 + |(x - x_m) - (x - x_n)|^2 &= 2|x - x_m|^2 + |x - x_n|^2,
\end{align*}
\]

hence
\[
|x_n - x_m|^2 = 2|x - x_m|^2 + 2|x - x_n|^2 - 4|x - \frac{1}{2}(x_m + x_n)|^2.
\]

But
\[
\frac{1}{2}(x_m + x_n) \in M \implies d \leq |x - \frac{1}{2}(x_m + x_n)| \leq \frac{1}{2}|x - x_m| + \frac{1}{2}|x - x_n| \to d
\]
as \(m, n \to \infty\), hence
\[
|x_n - x_m|^2 \to 0
\]
and \([x_n]\) is a Cauchy sequence.

Let \(x_o = \lim x_n\). Then \(x_o \in M\) since \(M\) is closed, and
\[
d \leq |x - x_o| \leq |x - x_n| + |x_n - x_o| \to d
\]
implies
\[
|x - x_o| = d.
\]

If \(x_o, x_1 \in M\) and
\[
|x - x_o| = |x - x_1| = d,
\]
then
\[
\frac{1}{2}(x_o + x_1) \in M \quad \text{and}
\]
\[
|x_o - x_1|^2 = 2|x - x_o|^2 + 2|x - x_1|^2 - 4|x - \frac{1}{2}(x_o + x_1)|^2 \leq 2d^2 + 2d^2 - 4d^2 = 0,
\]
hence
\[
|x_o - x_1| = 0
\]
and \(x_o = x_1\).

Now suppose \(x - x_o = z\) is not \(\perp\) to every vector in \(M\). Then there is a unit vector \(u \in M\) such that \(u \cdot z = \alpha \neq 0\) and it suffices to assume that \(\alpha > 0\) (otherwise use \(u e^{-1} \arg \alpha\)). Now \(y = x_o + \alpha u \in M\),

but
\[
|x - y|^2 = |z - \alpha u|^2 = |z|^2 - \alpha^2 = d^2 - \alpha^2 < d^2,
\]
which is a contradiction.

F. Riesz Representation Theorem. If \(f : X \to \mathbb{Z}\) is a continuous linear functional on a Hilbert space \(X\), then there exists a unique vector \(y \in X\) such that \(f(x) = x^*y\) for all \(x \in X\). Furthermore \(|y| = \sup |fx|\).

Proof. Let \(M = \{x : f(x) = 0\}\). Then \(M\) is a subspace since \(f\) is continuous. If \(M = X\), take \(y = \theta\). Otherwise, by the above theorem there exists a unit vector \(u \in M^\perp\), and
\[
M_u = [(fx)u - (fu)x : x \in X] \subseteq M.
\]
Therefore,
\[
[(fx)u - (fu)x] \cdot u = f(x) - (fu) x \cdot u = 0,
\]
and it suffices to let \(y = (fu)^*u\). If \(fx = x \cdot y_1 = x \cdot y_2\), then \(x \cdot (y_1 - y_2) = 0\) for all \(x\), hence \(y_1 = y_2\).

Now \(|fx| = |x \cdot y| \leq |x||y|\) by the Schwarz inequality, hence
sup |fx| ≤ |y|. But if y ≠ 0, then \( \frac{y}{|y|} = u \) is a unit vector and 
\[ fu = |y|, \text{ hence } \sup |fx| = |y| \text{ if } y \neq 0. \] If y = 0, this is trivially true.

This beautiful theorem, which completely characterizes all continuous linear functionals on Hilbert space, has many important applications. For example, suppose \( X : \Omega \to X \) is weakly measurable, where \((\Omega, \mathcal{A}, \mu)\) is a measure space, \(\sigma\)-finite or not, and \(X\) is a Hilbert space. This means \(X \cdot y\), hence also \(y \cdot X\), is a measurable scalar function for every \(y \in X\). If there exists a scalar function \(a(\omega)\) such that 
\[ |X(\omega)| \leq a(\omega) \in L_1, \] then

\[ g(y) = \int y \cdot X(\omega) \, d\mu(\omega). \]

exists and is a continuous linear functional on \(X\). Therefore, by the F. Riesz Representation Theorem, there is a unique vector \(z \in X\) such that 
\[ g(y) = y \cdot z, \] and by definition \(z = \int X \, d\mu\). This is called the Pettis integral, or weak integral, and its defining equation is

\[ y \cdot \int X = \int y \cdot X, \quad y \in X. \]

The Pettis integral may exist even when the Bochner integral does not. But it is easy to see that every Bochner summable function is Pettis summable; and the two integrals are equal since the defining equation of the Pettis integral holds for simple functions, hence also Bochner summable functions.

Suppose now that \(X\) is separable, and let \([y_n]\) be a basis. If \((\Omega, \mathcal{A}, \mu)\) is a \(\sigma\)-finite measure space, then it follows that every weakly
measurable function \( X : \Omega \to \mathbb{X} \) is strongly measurable, since

\[
x = \sum_n (X \cdot y_n) y_n
\]

and every partial sum is strongly measurable. Thus in this case a function is Bochner summable if and only if it is Pettis summable. Furthermore, \( \int_A X \in \mathcal{B} \) implies by the scalar case that \( X \cdot y_n \xrightarrow{a.s.} 0 \). Thus

\[
x = \sum_n (X \cdot y_n) y_n \xrightarrow{a.s.} 0
\]

since the union of a countable number of \( \mu \)-null sets is \( \mu \)-null. This will be shown in the next chapter for separable Banach spaces, using the Hahn-Banach Theorem.

Finally, consider the space \( \mathcal{L}^2 \) of all square summable functions \( X : \Omega \to \mathbb{X} \), and for \( X, Y \in \mathcal{L}^2 \) define

\[
X : Y = \int X \cdot Y.
\]

This is clearly an inner product, and \( X : X = \|X\|_2^2 \); hence an \( \mathcal{L}^2 \) space of Hilbert valued functions is again a Hilbert space, by the Riesz-Fischer Theorem.
CHAPTER IV

PROBABILITY THEORY

In this chapter, the material developed so far will be used to generalize some theorems of classical probability theory. Throughout the chapter, \((\Omega, \mathcal{A}, P)\) is an arbitrary probability space, and \((X, \mathcal{B})\) is a measurable space; usually \(X\) is a separable Hilbert or Banach space with norm topology \(\mathcal{U}\) and Borel \(\sigma\)-field \(\mathcal{B} = \overline{\mathcal{U}}\).

A random variable (r.v.) in \(X\) \((X\text{-valued r.v.})\) means a function \(X : \Omega \to X\) such that \(X^{-1}\mathcal{B} \subseteq \mathcal{A}\), and will be called a Hilbert r.v., or Banach r.v. according as \(X\) is a Hilbert or Banach space. The expectation (expt.) of a Banach r.v. \(X\) is defined as its Bochner integral whenever it exists, and is denoted by either \(EX\) or \(\int X\) according to convenience. The pr. distribution of a r.v. \(X\) is the pr. \(Q\) on \(\mathcal{B}\) defined by

\[
QB = P[X \in B] = PX^{-1}B \quad (B \in \mathcal{B}),
\]

and is usually denoted by \(P_X\).

Most of the theorems in this chapter are generalizations of theorems in LOEVE and in HALMOS [1], for real r.v.'s, to the case of Hilbert or Banach r.v.'s. The results concerning conditional expectations are mostly due to DRIML and HANS. For a more complete discussion of recent developments, see GRENAENDER.

A class \(\mathcal{M}\) of subsets of \(X\) is a monotone class iff, for every monotone sequence of sets \(A_n \in \mathcal{M}\), \(\lim A_n \in \mathcal{M}\).
If $\zeta$ is an arbitrary class of subsets of $X$, then by definition

$$\bar{\zeta} = \{B : \zeta \subseteq B, B \text{ is a } \sigma\text{-field}\}$$

$$\zeta = \{F : \zeta \subseteq F, F \text{ is a field}\}$$

$$\hat{\zeta} = \{M : \zeta \subseteq M, M \text{ is a monotone class}\}$$

It follows easily that $\bar{\zeta} = \hat{\zeta}$. Similarly, $\hat{\zeta}$ denotes the minimal ring containing $\zeta$, and $\zeta^S$ denotes the minimal $\sigma$-ring containing $\zeta$. A field $\zeta$ is a $\sigma$-field iff it is a monotone class, since $\bigcup A_n = \bigcup \bigcup A_k$.

Thus it is clear that $\bar{\zeta} \subseteq \hat{\zeta} = \bar{\zeta}$ for any class $\zeta$, and if $\hat{\zeta}$ is a field, then also $\bar{\zeta} \subseteq \hat{\zeta}$, hence $\bar{\zeta} = \hat{\zeta}$. These remarks, and the following theorem, remain true for rings, $\sigma$-rings, and $\zeta^S$ in place of fields, $\sigma$-fields, and $\bar{\zeta}$.

**Monotone Class Theorem.** If $\zeta$ is a field, so is $\hat{\zeta}$, and

$$\bar{\zeta} = \hat{\zeta}.$$

**Proof.** For each $B \in \zeta$, let $\zeta_B = \{A \in \zeta : A \subseteq B, A^C \subseteq B, AB \in \zeta\}$. It follows that $\zeta_B$ is a monotone class. If $B \in \zeta$, then $\zeta \subseteq \zeta_B$, hence $\bar{\zeta} \subseteq \zeta_B$. Thus if $A \in \hat{\zeta}$ is fixed, then $A \in \zeta_B$ for each $B \in \zeta$. This implies that $\zeta \subseteq \hat{\zeta}_A$, hence $\hat{\zeta} \subseteq \hat{\zeta}_A$. Therefore $\hat{\zeta} = \hat{\zeta}_A$ for each $A \in \zeta$, which implies that $\hat{\zeta}$ is a field.

One of the most important concepts in prob. theory is the concept of independence. Let the index $t$ vary over an arbitrary index set $T$, and suppose $\zeta_t \subseteq A$ are given classes of events. The classes $\zeta_t$ are said to be independent (ind.) with respect to the prob. $P$ iff, for every finite subset $[t_1, t_2, ..., t_n] \subseteq T$ of distinct indices and every choice
of events \( A_j \in \xi_{t_j} \),

\[
\bigcap_{j=1}^{n} A_j = \prod_{j=1}^{n} \mathbb{P} A_j.
\]

Random variables \( X_t : \Omega \rightarrow \mathbb{X} \) are independent iff the \( \sigma \)-fields \( X_t^{-1} \mathcal{G} \) are independent.

**Independence Theorem**

If \( \xi_t \) are independent classes closed under finite intersections, then \( \bar{\xi}_t \) are independent. Random variables \( X_t \) in a measurable space \((\mathbb{X}, \mathcal{E})\), where \( \mathcal{E} \) is closed under finite intersections, are independent iff \( \xi_t = X_t^{-1} \mathcal{E} \) are independent.

**Proof.** Assume without loss of generality that \( T = \{1, 2, \ldots, n\} \), and that \( \emptyset, \Omega \in \xi_k \). Consider first the case \( n = 2 \), and let

\[
\mathcal{M}_1 = \{ A_1 \in \xi_1 : P A_1 A_2 = P A_1 \cdot P A_2 \ for \ all \ A_2 \in \xi_2 \}.
\]

By hypothesis \( \xi_1 \subset \mathcal{M}_1 \), and it follows easily that \( \mathcal{M}_1 \) is closed under finite sums and proper differences; but it is not obvious that \( \mathcal{M}_1 \) is closed under finite intersections.

Let \( \xi'_1 \) be the class of all finite unions of \( \xi_1 \) sets. Then \( \xi'_1 \) is closed under finite unions and intersections; and it follows by induction that \( \xi'_1 \subset \mathcal{M}_1 \), using the fact that \( \xi_1 \) is closed under finite intersections.

Let \( \mathcal{D}_1 \) be the class of all proper differences of \( \xi'_1 \) sets, and let \( \mathcal{J}_1 \) be the class of all finite sums of \( \mathcal{D}_1 \) sets. Then \( \mathcal{J}_1 \subset \mathcal{M}_1 \), and \( \mathcal{J}_1 \) is a field (see Chapter VI); in fact \( \mathcal{J}_1 = \xi'_1 \). Finally, \( \mathcal{M}_1 \) is
a monotone class, hence \( \mathcal{F}_1 \subseteq \mathcal{M}_1 \) implies \( \mathcal{C}_1 = \mathcal{F}_1 = \mathcal{F}_1 \subseteq \mathcal{M}_1 \) by the Monotone Class theorem. Therefore \( \mathcal{C}_1 \) and \( \mathcal{C}_2 \) are independent. Since \( \mathcal{C}_1 \) is closed under finite intersections, it follows in the same way that \( \mathcal{C}_1 \) and \( \mathcal{C}_2 \) are independent.

Now suppose \( \mathcal{C}_1, \ldots, \mathcal{C}_{n-1} \) are independent, and let

\[
\xi_{n-1} = \left[ \bigcap_{k=1}^{n-1} A_k : A_k \in \mathcal{C}_k \right].
\]

Then \( \xi_{n-1} \) and \( \mathcal{C}_n \) are independent and closed under finite intersections, hence \( \xi_{n-1} \) and \( \mathcal{C}_n \) are independent. But

\[
\xi_{n-1} = \left[ \bigcup_{j=1}^{n-1} \mathcal{C}_j \right] = \left[ \bigcup_{j=1}^{n-1} \mathcal{C}_j \right],
\]

thus if \( A_j \in \mathcal{C}_j \) (\( j = 1, \ldots, n \)), then \( A_1 \cdots A_{n-1} \in \xi_{n-1} \) and

\[
P(A_1 \cdots A_{n-1})A_n = P(A_1 \cdots A_{n-1})PA_n = (P(A_1 \cdots PA_{n-1})PA_n)
\]

using the induction hypothesis. This completes the proof of the first assertion, and the second assertion follows from the first, using the definitions.

Let \( (X, \mathcal{B}) \) be a measurable space, \( X^n = \Pi_{j=1}^n X_j \),

\[
0 = n_0 < n_1 < \ldots < n_m = n, \quad \Delta n_i = n_i - n_{i-1}, \quad m_i = n_{i-1} + 1,
\]

and \( X^{\Delta n_i} = \Pi_{j=m_i}^{n_i} X_j \) (\( i = 1, \ldots, m \)), where \( X_j = X \). The projections \( q_i : X^n \rightarrow X^{\Delta n_i} \) are defined by \( q_i(x_1, \ldots, x_n) = (x_{m_i}, \ldots, x_{n_i}) \), \( \Delta n_i \)

is the class of all "rectangles" in \( X^{\Delta n_i} \) of the form \( \Pi_{j=m_i}^{n_i} B_j (B_j \in \mathcal{B}) \),

\[
\mathcal{B}^n = \mathcal{B}^{\Delta n_i}, \quad \text{and} \quad p_j(x_1, \ldots, x_n) = x_j. \quad \text{It follows that}
\]

\[
q_i^{-1} \mathcal{B} = \left[ q_i^{-1} \mathcal{C}_j \right] = \left[ \bigcup_{j=m_i}^{n_i} p_j^{-1} \mathcal{B} \right].
\]
A product probability on the product $\sigma$-field $\mathcal{B}^n = \left[ \bigcup_{j=1}^{n} p_j^{-1} \mathcal{B} \right]$ means a pr. $Q$ such that, if $B_j \in \mathcal{B}$ for $j = 1, \ldots, n$, then
$$Q \cap B_j = \bigcap_{j=1}^{n} q_j^{-1} \mathcal{B}_j.$$ The classes $q_j^{-1} \mathcal{B}_j \subset \mathcal{B}^n$ are closed under finite intersections and independent with respect to any product pr. $Q$ on $\mathcal{B}^n$. Therefore, by the Independence Theorem, the $\sigma$-fields $q_j^{-1} \mathcal{B}_j \subset \mathcal{B}^n$ are independent with respect to any product pr. In particular, suppose $(\mathcal{Y}, \zeta)$ is another measurable space, let $f_i : X^n \rightarrow \mathcal{Y}$ be Borel functions, and define the Borel functions $g_i : X^n \rightarrow \mathcal{Y}$ by $g_i = f_i q_i$. Then $g_i^{-1} \zeta \subset q_i^{-1} \mathcal{B}_i$, hence $g_i$ are independent with respect to any product pr. $Q$ on $\mathcal{B}^n$.

Borel Functions Theorem

If $X_j : \Omega \rightarrow X$ are independent r.v.'s $(j = 1, \ldots, n)$ and $f_i : X^\mathcal{B}_i \rightarrow \mathcal{Y}$ are Borel functions $(i = 1, \ldots, m)$, then
$$Y_i = f_i(X_{n_1}, \ldots, X_{n_i}) : \Omega \rightarrow \mathcal{Y}$$ are also independent.

Proof. Let $X = (X_j : j = 1, \ldots, n) : \Omega \rightarrow X^n$ be the vector function with component functions $X_j$, and let $P_X$ be the pr. distribution of $X$. Then $P_X$ is a product pr. on $\mathcal{B}^n$, for if $B_j \in \mathcal{B}$, then
$$P_{X_j} B_j = P_X P_{X_j}^{-1} B_j = \bigcap_{j=1}^{n} P_X^{-1} B_j = P_X P_{X_j}^{-1} B_j = \bigcap_{j=1}^{n} P_X^{-1} B_j = \bigcap_{j=1}^{n} P_Y^{-1} C_i.$$ since $X_j$ are independent.

Using the previous notation, $Y_i = g_i X_i$; thus if $C_i \in \zeta$, then
$$P \bigcap_{i=1}^{m} Y_i^{-1} C_i = P_X \bigcap_{i=1}^{m} g_i^{-1} C_i = \bigcap_{i=1}^{m} P_X g_i^{-1} C_i = \bigcap_{i=1}^{m} P_Y^{-1} C_i$$ since $g_i$ are independent with respect to the product pr. $P_X$. \(\blacksquare\)
Change of Variables Theorem

Suppose \((X, \mathcal{B})\) is a measurable space and \(Y\) is a separable Banach space with norm topology \(\mathcal{U}\) and Borel \(\sigma\)-field \(\mathcal{C} = \mathcal{V}\), and let \(X : \Omega \rightarrow X\), \(f : X \rightarrow Y\) be r.v.'s. Then

\[
\int_{\Omega} f(X(\omega))dP = \int_X f(x)dP_X
\]

whenever either side exists.

**Proof.** Suppose first that \(f(x) = yIB\), where \(y \in Y\) and \(B \in \mathcal{B}\). Then \(f_X(\omega) = yIB[X(\omega)] = yIX^{-1}B\), and asserted equation becomes \(yPX^{-1}B = yP_XB\), which is true by definition of \(P_X\); it follows easily that the integrals are equal whenever \(f\) is a simple function. If \(Y = \mathbb{R}\) and \(f \in M^+\), the conclusion follows from the MCT; thus in any case the integrals are equal when the integrands are replaced by their norms, so that the existence of either side implies that of the other. But if the integral on the right exists, then there is a sequence \([f_n]\) of simple functions such that \(f_n \xrightarrow{a.s.} f\) and \(|f_n| \leq g \in L^+\), so the conclusion follows by the DCT.

Multiplication Theorem

Let \(X\) be a separable Hilbert space, and suppose \(X, Y : \Omega \rightarrow X\) are independent r.v.'s whose expectations exist. Then \(EX \cdot Y\) exists, and

\[EX \cdot Y = EX \cdot EY\]

**Proof.** The theorem is true for elementary functions, and if \(X = \mathbb{R}\) and \(X, Y \in M^+\) the result follows by the MCT. But in any case \(|X|\) and
are independent by the Borel Functions Theorem, hence
\[ E|X||Y| = E|X|E|Y| < \infty, \]
so that \( EX \cdot Y \) exists. Now choose sequences
\( X_n, Y_n \) of elementary functions such that \( X_n \) and \( Y_n \) are independent
for each \( n \), \( |X_n| \leq |X| + 1, |Y_n| \leq |Y| + 1 \), \( X_n \overset{a.s.}{\to} X \), and
\( Y_n \overset{a.s.}{\to} Y \); and apply the DCT.

Note that if \( X \) is the complex plane and \( X, Y \) are independent,
then \( X, Y^* \) are independent, \( X \cdot Y^* = XY \), and the theorem says that
\( EXY = EXEY \). This extends by induction to \( n \) factors.

Let \( \mathcal{G} \) be a \( \sigma \)-field such that \( \mathcal{G} \subseteq \mathcal{A} \), and let \( P_{\mathcal{G}} \) denote
the restriction of \( P \) to \( \mathcal{G} \). If \( X : \Omega \to \mathcal{X} \) is a Banach-valued, Bochner
summable r.v., then the conditional expectation (c. expt.) of \( X \) given
\( \mathcal{G} \) is an \((\mathcal{G}, \mathbb{B})\) measurable r.v., denoted by \( E_{\mathcal{G}} X \) and determined up
to a \( P_{\mathcal{G}} \) equivalence by
\[ \int_S (E_{\mathcal{G}} X) dP = \int_S X dP \ (S \in \mathcal{G}). \]

This definition will be justified below.

In case \( \mathcal{X} = \mathbb{Z} \), the existence and uniqueness (up to a \( P_{\mathcal{G}} \) equivalence)
of \( E_{\mathcal{G}} X \) follows from the Radon-Nikodym Theorem applied to the
\( P \)-continuous scalar measure \( \varphi : \mathcal{G} \to \mathbb{Z} \) defined by \( \varphi S = \int_S X dP \). In
fact, if \( \mathcal{X} = \mathbb{R} \) and \( EX = \infty \) exists, then \( \varphi \) is still \( P \)-continuous
(but not necessarily \( \sigma \)-finite); in this case \( E_{\mathcal{G}} X \) still exists by the
extended R-N theorem (LOEVE, p. 133), but is not necessarily finite up
to a \( P_{\mathcal{G}} \) equivalence.

All equations, inequalities, and convergences involving condi-
tional expectations are supposed to hold up to a \( P_{\mathcal{G}} \) equivalence, but
this will be understood rather than indicated each time. It will also
be assumed that all r.v.'s under consideration are \( (\mathcal{A}, \mathcal{B}) \) measurable, and that their expectations exist.

If \( X = \mathbb{R} \) and \( 0 \leq X_n \uparrow X \), then \( 0 \leq \mathbb{E}^\mathbb{P} X_n \uparrow Y \in \mathcal{M}(\mathcal{G}, \mathcal{B}) \), hence \( \int_S X = \lim_S \int_S X_n = \lim_S \int_S \mathbb{E}^\mathbb{P} X_n = \int_S Y \) by the usual MCT; therefore \( Y = \mathbb{E}^\mathbb{P} X \), so that the MCT holds (up to a \( \mathbb{P}_\mathcal{G} \) equivalence) for conditional expectations. The DCT in the real case follows from the MCT and the a.s. additivity of \( \mathbb{E}^\mathbb{P} \), and the complex case follows from the real case.

Denote by \( \mathcal{L}^\mathbb{P} \) the family of all \( \mathbb{P} \)-equivalence classes of \( (\mathcal{A}, \mathcal{B}) \)-measurable, summable r.v.'s \( X \) such that \( \mathbb{E}^\mathbb{P} X \) exists; and let \( \mathcal{L}_Y \) be the family of all \( \mathbb{P}_\mathcal{G} \)-equivalence classes of \( (\mathcal{G}, \mathcal{B}) \)-measurable r.v.'s \( Y \) such that \( \mathbb{E}^\mathbb{P} Y \) exists.

**Conditional Expectations Theorem**

1. If \( X \in \mathcal{L}^\mathbb{P} \) and \( f : X \rightarrow Z \) is a continuous linear functional, then
   \[
   \mathbb{E}^\mathbb{P} fX = f\mathbb{E}^\mathbb{P} X.
   \]

2. If \( X \) is a separable Hilbert space, \( X \in \mathcal{L}^\mathbb{P} \), \( Y \in \mathcal{L}_Y \), and
   \[
   \int |X||Y| < \infty,
   \]
   then
   \[
   \mathbb{E}^\mathbb{P} X^*Y = X^*\mathbb{E}^\mathbb{P} Y.
   \]

3. If \( X \in \mathcal{L}^\mathbb{P} \), then \( |\mathbb{E}^\mathbb{P} X| \leq \mathbb{E}^\mathbb{P} |X| \).

4. \( \mathbb{E}^\mathbb{P} : \mathcal{L}^\mathbb{P} \rightarrow \mathcal{L}_Y \) is a continuous linear transformation.

5. If \( X_n \in \mathcal{L}^\mathbb{P} \), \( |X_n| \leq g \in \mathcal{L}_+ \), and \( \overset{\text{a.s.}}{\longrightarrow} X \), then \( X_n \in \mathcal{L}^\mathbb{P} \) and \( \mathbb{E}^\mathbb{P} X_n \rightarrow \mathbb{E}^\mathbb{P} X \) (DCT); this implies that
\[ L^g = L. \]

Proof. Except for (2), the proof is patterned after the one in DRIML and HANS, who consider a real separable Banach space \( X \).

(1) The proof of (1) follows immediately, since \( f \in L^g X \) is \((\mathcal{G}, \mathcal{B})\)-measurable and

\[ \int_S E^g X = \int_S X \implies \int_S fE^g X = \int_S fX. \]

(2) First suppose \( X = Z \), and let \( X = IA, A \in \mathcal{G} \). Then for each \( S \in \mathcal{G} \),

\[ \int_S (IA)E^g Y = \int_{AS} E^g Y = \int_{AS} Y = \int_S (IA)Y. \]

The assertion follows for simple functions \( X \), and then for \( X \in L^g \) by the DCT.

For let \( \{y_n\} \) be a basis for \( X \), and write

\[ X_n = \sum_{k=1}^{n} (X \cdot y_k)y_k; \text{ so that } X_n \to X, \]

\[ X_n \cdot Y = \sum_{k=1}^{n} (X \cdot y_k)(y_k \cdot Y) \to X \cdot Y, \]

and \( |X_n \cdot Y| \leq |X| |Y| \). Since \( X \cdot y_k \) is \((\mathcal{G}, \mathcal{B})\)-measurable and

\[ E^g (y_k \cdot Y) = y_k \cdot E^g Y, \]

it follows from the scalar case that

\[ E^g X_n \cdot Y = \sum_{k=1}^{n} (X \cdot y_k) E^g (y_k \cdot Y) = X_n \cdot E^g Y. \]

(3) First suppose \( X = Z \), and write \( E^g X = |E^g X| e^{i\alpha} \), where

\[ e^{i\alpha} = 1 \text{ whenever } E^g X = 0. \]

Then \( e^{-i\alpha} \) is \((\mathcal{G}, \mathcal{B})\)-measurable, and using (2) it follows that
62

\(|E^S S| = e^{-ia} E^S X = E^S e^{-ia} X = E^S \text{Re } [e^{-ia} X] \leq E^S |X| .

It will be shown in the next chapter, using the Hahn-Banach Theorem, that there exists a countable set \([f_n]\) of continuous linear functionals on \(X\) such that \(|x| = \sup |f_n x|\) for every \(x \in X\). In case \(X\) is a separable Hilbert space it suffices to take \(f_n(x) = x^\ast v_n\), where \([v_n]\) is a countable dense set of nonzero vectors and \(u_n = \frac{v_n}{|v_n|}\). Now using (1) and the scalar case,

\[|f_n E^S X| = |E^S f_n X| \leq E^S |f_n X| \leq E^S |X| ,\]

which yields

\(|E^S X| = \sup |f_n E^S X| \leq E^S |X| .

(4) If \(E^S X\) and \(E^S Y\) exist, then it follows immediately from the definition that \(\alpha E^S X + \beta E^S Y\) is a conditional expectation for \(\alpha X + \beta Y\). To show that \(E^S : L^S \rightarrow L^S\) is a function, it must be shown that \(E^S X\) is uniquely determined (up to a \(P^S\) equivalence) whenever it exists. Suppose \(Y \in L^S\) and \(\int_S Y = 0\) for all \(S \in S\), and let \([f_n]\) be the set of functionals in (3). Then using (1),

\(f_n \int_S Y = \int_S f_n Y = 0\), so that \(f_n Y \overset{a.S.}{\to} 0\) for each \(n\) by the scalar case, whence \(|Y| = \sup |f_n Y| \overset{a.S.}{\to} 0 \supset Y \overset{a.S.}{\to} 0\). This proves the uniqueness, so \(E^S\) is a linear transformation.

The spaces \(L^S, L^S \subset L\) are clearly NLS's with the usual norm \(|X| = \int |X|\). Suppose \(X_n \in L^S\) and \(|X_n| \rightarrow 0\). Using (3),

\(|E^S X_n| = \int |E^S X_n| \leq \int E^S |X_n| = \int |X_n| \rightarrow 0 .\)
(5) Let \( f_n = \sup_{k \geq n} |X_k - X| \), so that \( |f_n| \leq 2g \) and \( f_n \to 0 \) a.s., hence \( E^g f_n \to 0 \) a.s. by the DCT for the scalar case. Thus if \( m < n \), then

\[
|E^g X_n - E^g X_m| \leq E^g |X_n - X_m| \leq 2E^g f_m \to 0 \quad (m,n \to \infty),
\]

so that \( E^g X_n \overset{a.s.}{\to} Y \) since \( X \) is complete. Since each \( E^g X_n \) is strongly \( (\mathcal{G}, \mathcal{B}) \)-measurable, it follows from the results of the previous chapter that \( Y \) is strongly \( (\mathcal{G}, \mathcal{B}) \)-measurable. It will be shown in the next chapter that every strongly \( (\mathcal{G}, \mathcal{B}) \)-measurable function \( Y \) is \( (\mathcal{G}, \mathcal{B}) \)-measurable in the sense that \( Y^{-1} \mathcal{B} \subseteq \mathcal{G} \); in case \( X \) is a separable Hilbert space, this follows from

\[
Y^{-1}[x : |x - x_0| < \varepsilon] = [\omega : \Sigma|Y(\omega) \cdot y_n - x_0 \cdot y_n|^2 < \varepsilon^2] \in \mathcal{B},
\]

where \([y_n]\) is a basis.

Since \( |E^g X_n| \leq E^g |X_n| \leq E^g g \), it follows by the DCT for Bochner integrals that

\[
\int_S Y = \lim \int_S E^g X_n = \lim \int_S X_n = \int_S X,
\]

therefore \( E^g X_n \overset{a.s.}{\to} E^g X = Y \).

Finally, if \( X \in \mathcal{L} \), then there exists a sequence of simple functions \( X_n \) such that

\[
|X_n| \leq |X| + \varepsilon \quad \text{and} \quad X_n \overset{a.s.}{\to} X.
\]

But it follows easily that \( E^g X_n \) exists for each \( n \), hence \( E^g X \overset{a.s.}{\to} \lim E^g X_n \) exists by the DCT just established, and \( \mathcal{L}^g = \mathcal{L} \).
The following two classical lemmas will be needed to prove the Law of Large Numbers.

**Toeplitz lemma.** If
\[ \sum_{k=1}^{n} a_k = b_n \uparrow \infty \quad \text{and} \quad y_n = \sum_{k=1}^{n} a_k x_k, \]
then
\[ x_n \rightarrow x \quad \Rightarrow \quad \frac{y_n}{b_n} \rightarrow x. \]

**Proof.** Suppose first that \( x_n \rightarrow \theta \), let \( \varepsilon > 0 \), choose \( m \) so that
\[ k \geq m \quad \Rightarrow \quad |x_k| < \varepsilon, \]
and let \( \sum_{k=1}^{m} a_k |x_k| = M. \) Then for \( n > m \),
\[ \left| \frac{y_n}{b_n} \right| = \frac{1}{b_n} \sum_{k=1}^{m} a_k |x_k| + \frac{1}{b_n} \sum_{k=m+1}^{n} a_k |x_k| \leq \frac{M}{b_n} + \varepsilon \rightarrow \varepsilon \quad (n \rightarrow \infty). \]
Thus \( x_n \rightarrow \theta \quad \Rightarrow \quad \frac{y_n}{b_n} \rightarrow \theta. \)

Now if \( x_n \rightarrow x \), then \( x_n - x \rightarrow \theta \), whence
\[ \frac{y_n}{b_n} - x = \frac{1}{b_n} \sum_{k=1}^{n} a_k (x_k - x) \rightarrow \theta. \]

**Kronecker's lemma.** If
\[ b_n \uparrow \infty, \quad s_n = \sum_{k=1}^{n} x_k, \quad \text{and} \quad v \in \mathbb{X}, \]
then
\[ \sum_{k=1}^{n} \frac{x_k}{b_n} = v \quad \Rightarrow \quad \frac{s_n}{b_n} \rightarrow \theta. \]

**Proof.** Replace \( x_n \) by \( b_n x_n \); and let \( v_n = \sum_{k=1}^{n} x_k \), \( v_0 = x_0 = \theta \),
and \( s_n = \sum_{k=1}^{n} b_k x_k \). It suffices to show that \( v_n \rightarrow v \quad \Rightarrow \quad \frac{s_n}{b_n} \rightarrow \theta. \)

Summation by parts yields
\[ s_n = \sum_{k=1}^{n} b_k (v_k - v_{k-1}) = b_n v_n - \sum_{k=1}^{n} (b_k - b_{k-1}) v_{k-1}, \]

whence \[ \frac{s_n}{b_n} = \frac{v_n - v_{n-1}}{b_n} \rightarrow v - v = \theta, \] applying the Toeplitz lemma with \[ b_k - b_{k-1} = a_k \text{ and } x_k \text{ replaced by } v_{k-1}. \]

Throughout the remainder of this chapter, \( X \) is supposed to be a separable Hilbert space, and \( \|X\| \) denotes that \( L^2 \) norm of a r.v. \( X \).

Recall that \( L^2 \) is also a Hilbert space with inner product defined by \( X : Y = EX \cdot Y \).

Convergence of sequences and series in \( L^2 \) norm will be denoted by \( X_n \xrightarrow{2} X \) and \( \Sigma X_n \subseteq X \) respectively. If \( X_n \) is an orthogonal sequence in \( L^2 \) and \( S_n = \sum_{k=1}^{n} X_k \), then

\[ \|S_n - S_m\|^2 = \sum_{k=m+1}^{n} \|X_k\|^2, \]

hence \( S_n - S_m \xrightarrow{2} \theta \) iff \( \Sigma \|X_n\|^2 < \infty \). Furthermore, if \( S_n \xrightarrow{2} X \), that is \( X \subseteq \Sigma X_n \), then \( \|X\|^2 = \Sigma \|X_n\|^2 \).

Suppose \( b_n \uparrow \infty \) and \( \sum \frac{\|X_n\|^2}{b_n^2} < \infty \), so that \( \sum \frac{X_n^2}{b_n} \subseteq Y \). Then \( \frac{S_n}{b_n} \xrightarrow{2} \theta \) by Kronecker's lemma, hence

\[ p \left( \left| \frac{S_n}{b_n} \right| \geq \varepsilon \right) \leq \frac{\|S_n\|^2}{b_n^2 \varepsilon^2} \rightarrow 0 \quad \Rightarrow \quad \frac{S_n}{b_n} \xrightarrow{p} \theta \]

by Tchebychev's inequality. Thus the following theorem holds.

**Bernouilli-Tchebychev (Weak) Law of Large Numbers**

If \( X_n \) are orthogonal r.v.'s and \( b_n \uparrow \infty \), then
In particular,

$$\sum \frac{\|X_n\|^2}{b_n^2} < \infty \implies \frac{S_n}{b_n} \xrightarrow{P} \theta.$$ 

If $X$ is a r.v. whose expectation exists, then the variance of $X$ is defined by

$$\sigma_X^2 = \|X - EX\|^2 = \|X\|^2 - |EX|^2$$

A r.v. $X$ is said to be centered at expectation iff $EX = \theta$; in this case $\sigma_X^2 = \|X\|^2$.

Let $X_n$ be summable Hilbert r.v.'s, $\mathcal{G}_n = \left[ \bigcup_{k=1}^{n-1} \mathcal{X}_k \right]$ (n=2,3,...), $\mathcal{G}_1 = [\emptyset, \Omega]$, $\xi_n = E\mathcal{G}_n X_n$ (n = 2,3,...), and $\xi_1 = EX_1$; $\xi_n$ are called the conditional expectations of $X_n$ (given the predecessors), and $X_n$ are said to be centered at conditional expectations iff $\xi_n \stackrel{a.s.}{=} \theta$. (This method is due to the famous French mathematician P. Levy.)

Suppose $X_n$ are centered at c. expt.'s and $m < n$. Then $X_n$ are centerred at expt.'s ($EX = E\xi_n = \theta$) and $E\mathcal{G}_n X_n = X_m : \mathcal{G}_n X_n = 0$ since $X_m$ is $\mathcal{G}_n$ measurable; therefore $EX_m = X_m : X_n = 0$.

**Bienayme Equation**

If $X_n$ are centered at c. expt.'s, then they are centered at expt.'s and orthogonal, hence

$$\|S_n\|^2 = \sum_{k=1}^{n} \|X_k\|^2.$$
It should be noted that if $X_n$ are independent, then $X_n^{-1}B$ and $\mathcal{G}_n$ are independent for each $n$; and in this case $E^B_X X_n \overset{a.s.}{=} E X_n$, so that centering at conditional expectations reduces to centering at expectations. For if $[y_k]$ is a basis for $X$, then $X_n \cdot y_k$ and $IS$ are independent for each $k$ and each $S \in \mathcal{G}_n$, using the Borel Functions Theorem; therefore $E(X_n \cdot y_k)IS = E(X_n \cdot y_k)PS$ by the Multiplication Theorem, which implies that $\int_S E X_n = (EX_n)PS = \int_S X_n$.

Since $\xi_n$ is $(\mathcal{G}_n, \mathcal{B})$ measurable, so is $|\xi_n|^2$, and

$$E^B_X |X_n - \xi_n|^2 = E^B_X |X_n|^2 - 2Re E^B_X \xi_n \cdot X_n + E^B_X |\xi_n|^2$$

$$= E^B_X |X_n|^2 - 2Re \xi_n \cdot E^B_X X_n + |\xi_n|^2$$

$$= E^B_X |X_n|^2 - |\xi_n|^2,$$

hence

$$\|X_n - \xi_n\|^2 = \|X_n\|^2 - |\xi_n|^2.$$

Now $|EX_n|^2 = |E\xi_n|^2 \leq (E|\xi_n|)^2 \leq |\xi_n|^2$, hence

$$\|X_n - \xi_n\|^2 = \|X_n\|^2 - |\xi_n|^2 \leq \|X_n\|^2 - |EX_n|^2$$

$$= \|X_n - EX_n\|^2 = \sigma^2 X_n.$$

That is, centering at condition expectations may modify variances, but they can only become smaller.

**Kolmogorov's Inequality**

If $X_n$ are centered at c. expt.'s and $S_n = \sum_{k=1}^n X_k$, then
\[ P \bigcup_{k=m}^{n} \left( |S_k - S_m| \geq \varepsilon \right) \leq \frac{1}{\varepsilon^2} \sum_{k=m}^{n} \|X_k\|^2. \]

**Proof.** It suffices to assume that \( m = 0 \), where \( S_0 = X_0 = \emptyset \). Let

\[ A_k = \bigcap_{j=1}^{k} \left( |S_j| < \varepsilon \right) \quad (k = 1, \ldots, n), \quad A_0 = \Omega, \]

and

\[ B_k = A_{k-1} - A_k = \bigcap_{j=1}^{k-1} \left( |S_j| < \varepsilon \right) \cap \left( |S_k| \geq \varepsilon \right). \]

Then \( A_k \nrightarrow \), hence \( \sum_{k=1}^{n} B_k = A_0 - A_n = A_n^c = \bigcup_{j=1}^{n} \left( |S_j| \geq \varepsilon \right) \).

Consider \( f(S_1, \ldots, S_k) = S_k^IB_k \), and note that

\[ f(x_1, \ldots, x_k) = \prod_{j=1}^{k-1} I\left(|X_j| < \varepsilon\right) I\left(|X_k| \geq \varepsilon\right) \]

is a Borel function and each \( S_j (j = 1, \ldots, k) \) is \( \mathcal{G}_{k+1} \) measurable, where

\[ \mathcal{G}_{k+1} = \left( \bigcup_{j=1}^{k} X_j^{-1} \mathcal{B} \right)^{-} \]; thus \( S_k^IB_k \) is also \( \mathcal{G}_{k+1} \) measurable. Hence

\[ E \mathcal{G}_{k+1} (S_k^IB_k) (S_n - S_k) = S_k^IB_k \cdot E \mathcal{G}_{k+1} (S_n - S_k) = 0 \]

since \( E \mathcal{G}_{k+1} X_j = E \mathcal{G}_{j} X_j = \emptyset \) for \( j \geq k + 1 \), which implies

\[ E(S_k^IB_k) (S_n - S_k) = \int_{B_k} S_k^i (S_n - S_k) = 0. \]

Therefore

\[ \int_{B_k} |S_n|^2 = \int_{B_k} |S_n - S_k|^2 + 2Re \int_{B_k} (S_n - S_k)^* S_k + \int_{B_k} |S_k|^2 \geq \int_{B_k} |S_k|^2 \geq \varepsilon^2 P B_k, \]
so that

\[ \varepsilon^2 p_{A_n} = \varepsilon^2 \sum_{k=1}^{n} b_k \leq \sum_{k=1}^{n} \frac{\| S_n \|^2}{b_k} = \| S_n \|^2 = \sum_{k=1}^{n} \| x_k \|^2. \]

**Borel-Kolmogorov-Levy (Strong) Law of Large Numbers**

1. If \( X_n \) are Hilbert r.v.'s centered at c. expt.'s then

\[ \sum_{k=m}^{n} \frac{\| x_k \|^2}{b_k^2} < \infty \Delta \sum_{k=m}^{n} \frac{b_k}{b_n} \to s. \quad S_n \to \sigma^2 \]

Proof. To prove (1), let \( S_n' = \sum_{k=1}^{n} \frac{x_k}{b_k} \), and note that

\[ P \left( \bigcup_{k=m}^{n} \left| S_k' - S_m' \right| \geq \varepsilon \right) \leq \frac{1}{\varepsilon^2} \sum_{k=m}^{n} \frac{\| x_k \|^2}{b_k^2} \]

for every \( \varepsilon > 0 \) by Kolmogorov's inequality, hence

\[ P \left( \bigcup_{k=m}^{n} \left| S_k' - S_m' \right| \geq \varepsilon \right) \leq \frac{1}{\varepsilon^2} \sum_{k=m}^{n} \frac{\| x_k \|^2}{b_k^2} \to 0 \quad (m \to \infty) \]

by the Continuity Theorem. It follows from the Convergences Theorem that \( S_n' - S_m' \to \sigma^2 \), so that \( S_n' \to \sigma^2 Y \) for some \( Y \) since \( X \) is complete. Therefore \( S_n \to \sigma^2 \) by Kronecker's lemma.

Since \( \| x_n' - x_n \|^2 \leq \sigma^2 x_n' \) it follows that in any case
\[
\sum_{n} \frac{\sigma^2 X_n^2}{b_n^2} < \infty \Rightarrow \frac{1}{b_n} \sum_{k=1}^{n} (X_k - \xi_k) \xrightarrow{a.s.} 0.
\]

The proof of (2) will not be given here, since it is almost exactly like the classical proof (see LOEVE, p. 239). It should be noted that (2) is also true for Banach r.v.'s. GRENANDER, p. 144 shows that the proof can be reduced to the case of elementary r.v.'s, and then to the case of finite dimensional r.v.'s, which is covered by the Hilbert valued case for \( X = \mathbb{Z}^n \) since all finite dimensional topological linear spaces are topologically isomorphic to \( \mathbb{Z}^n \).
CHAPTER V

FUNCTIONAL ANALYSIS AND TOPOLOGY

In this chapter are presented those parts of topology and functional analysis which seem to be necessary for an understanding of the recent literature on generalized random variables. Among the results presented are two of the most celebrated and powerful theorems of modern analysis: the Hahn-Banach Theorem and the Tychonov Product Theorem. Although most of the theorems in this chapter are well known, their proofs will nevertheless be given for the sake of completeness.

For more comprehensive treatments of the topics presented here see AKHIESER [1], BANACH, DUNFORD and SCHWARTZ, HILLE and PHILLIPS, KOLMOGOROV and FOMIN, LIUSTERNIK and SOBOLEV, LOOMIS, NAIMARK, RIESZ and SZ. NAGY, TAYLOR, and ZAANEN [2] for the functional analysis; and KELLEY for the topology. Excellent accounts of both topics can be found in McSHANE and BOTTS, and in SIMMONS. LOEVE also has a brief but lucid section on topology.

Functional Analysis

Throughout the present chapter, \( \mathcal{X} \) denotes either a NLS or a topological space, or both. The meaning will always be clear from the context.

Let \( \mathcal{X} \) and \( \mathcal{Y} \) be two NLS's with the same scalar field \( \mathbb{Z} \). A transformation \( T : \mathcal{X} \to \mathcal{Y} \) is said to be **bounded** iff it maps bounded sets in \( \mathcal{X} \) onto bounded sets in \( \mathcal{Y} \). If \( T \) is semihomogeneous
(\text{T}x = \alpha \text{T}x \text{ for } \alpha \geq 0), \text{ then } \text{T} \text{ is bounded iff the image of the unit sphere is bounded.}

**Boundedness Theorem.** A semihomogeneous transformation \( \text{T} \) is bounded iff either

1. \( |\text{T}x| \leq \beta |x| \) for some constant \( \beta \geq 0 \), or
2. \( \text{T} \) is continuous at the origin \( \theta \).

**Proof.** The sufficiency of condition (1) is obvious. To prove the necessity, suppose there is no such constant \( \beta \). Then for every \( n = 1, 2, \ldots \) there is an \( x_n \) in \( X \) such that \( |\text{T}x_n| > n^2 |x_n| \). Hence \( |\text{T}v_n| > n \), where \( v_n = \frac{x_n}{n|x_n|} \), which implies that \( \text{T} \) is not bounded.

The necessity of condition (2) is obvious, since \( |\text{T}x| \leq \beta |x| \) clearly implies that \( \text{T} \) is continuous at \( \theta \). To prove the sufficiency, suppose \( \text{T} \) is not bounded. Then as above there is a sequence of vectors \( v_n \) such that \( v_n \rightarrow \theta \), while \( |\text{T}v_n| > n \), hence \( \text{T} \) is not continuous at \( \theta \). Thus (1) and (2) are both equivalent to the boundedness of \( \text{T} \). It follows that a linear transformation \( \text{T} \), or a sublinear functional \( f \), is continuous iff it is bounded.

The **norm** of a s. homog. transformation \( \text{T} \) is defined by

\[
|\text{T}| = \inf \{ \beta : |\text{T}x| \leq \beta |x| \}. \text{ Thus } \text{T} \text{ is bounded iff } |\text{T}| < \infty. \text{ It follows that }
\]

\[
|\text{T}| = \sup \frac{|\text{T}x|}{|x| = 1}, \text{ and } |\text{T}x| \leq |\text{T}||x|. 
\]

To show this, note that \( B = \{ \beta : |\text{T}x| \leq \beta |x| \} = \{ \beta : |\text{T}u| \leq \beta \text{ for } |u| = 1 \} \). Now for \( \beta \in B \), \( |\text{T}u| \leq \beta \) whenever \( |u| = 1 \), which implies that \( |\text{T}|^* = \sup |\text{T}u| \leq \beta \) and hence \( |\text{T}|^* \leq \inf B = |\text{T}| \). But clearly \( |\text{T}u| \leq |\text{T}|^* \) whenever \( |u| = 1 \), so it follows that \( |\text{T}|^* \in B \), and thus
The space of all bounded linear functionals \( f : X \to \mathbb{Z} \) is called the **conjugate space** (or **adjoint space**) of \( X \). It will be denoted by \( X' \), and its elements will be denoted by \( x', y' \) or \( f, g \), with or without indices, according to convenience. The conjugate space \( X' \) can be considered as a NLS, where the functionals \( x' + y', \alpha x' \) are defined by \((x' + y')x = x'x + y'x\), \((\alpha x')x = \alpha (x'x)\) respectively and the norm of \( x' \) is \( |x'| = \sup_{|x| = 1} |x'x| \). Clearly \( |\alpha x'| = |\alpha||x'| \), \( |x' + y'| \leq |x'| + |y'| \), and \( |x'| = 0 \Leftrightarrow x' = 0' \), where \( 0'x = 0 \).

Note that \( X' \) is a space of functions \( x' : X \to \mathbb{Z} \), and thus an element \( x' \in X' \) has two meanings: (1) \( x' \) is a vector in the NLS \( X' \), and (2) \( x' \) is a scalar-valued function on the NLS \( X \). For this reason it is necessary to distinguish between the norm \( |x'| \) of \( x' \) considered as a vector, and the absolute value function associated with \( x' \) considered as a function, whose value at \( x \) is \( |x'x| \). Thus the latter will be denoted by \( |x'| \), so that \( |x'| : X \to \mathbb{Z} \) and \( |x'|(x) \leq |x'x| \).

It will not be necessary to talk about the absolute value function \( |x'| \) very often anyway, but its values \( |x'x| \) do occur frequently. No confusion will arise if it is noted that \( x' \), appearing by itself, always means a vector (which happens to be a scalar valued function), whereas \( x'x = x'(x) \), appearing in this form, always means a scalar.

**Conjugate Space Theorem.** \( X' \) is always a Banach space.

**Proof.** Let \( [x'_n] \) be a Cauchy sequence in \( X' \). Then \( |x'_m - x'_n| = \sup |x'_m x - x'_n x| \to 0 \), hence \( [x'_n x] \) is a Cauchy sequence for every unit \( |x| = 1 \).
vector $x$; and in fact for every vector $x$ since $x'\theta = 0$ and $x_n'x = \frac{x|x'x|}{|x|}$ for $x \neq \theta$. Therefore, since $\mathcal{Z}$ is complete, for each fixed $x$ the sequence $[x_n'x]$ converges to some scalar, which will be denoted by $x'x$. It suffices to show that the functional $x'$, defined by $x'x = \lim x_n'x$, is linear and bounded, since $|x_n' - x'| = \sup |x_n'x - x'x| \to 0$. Now

$$x'(\alpha x + \beta y) = \lim x_n'(\alpha x + \beta y) = \lim (\alpha x_n'x + \beta x_n'y) = \alpha x'x + \beta x'y,$$

hence $x'$ is linear. Note that $x_n'x \to x'x$ uniformly on the unit sphere $|x| = 1$, and $|x'x| \leq |x'x - x_n'x| + |x_n'x|$. Thus if $m$ is chosen so that $|x'x - x_m'x| \leq 1$ uniformly for $|x| = 1$, then

$$|x'| = \sup |x'x| \leq \sup |x'x - x_m'x| + \sup |x_m'x| \leq 1 + |x_m'| < \infty.$$  

The zero functional $\Theta'$, defined by $\Theta'x = 0$, is clearly in $X'$, but it is not so obvious that there exist others. For later purposes it is desirable to know that if $x_0$ is any point in $X$, then there exists a functional $f \in X'$ such that $f(x_0) = |x_0|$ and $|f| = 1$. This result is a corollary of the following celebrated theorem.

**Hahn-Banach Theorem.** Suppose $X$ is a NLS, $M$ is a linear manifold in $X$, and $f_0$ is a bounded linear functional on $M$. Then there exists a bounded linear functional $f \in X'$ such that:

1. $f(x) = f_0(x)$ for all $x$ in $M$
2. $|f| = |f_0|$.

The real case was proved independently by H. HAHN (1927) and S. BANACH.
(1929); then the complex case was proved by H. F. BOHNENBLUST and A. SOBEZYK (1938), also independently, using the real case. The proof is based on the following ingenious lemma.

**Lemma.** Suppose $X$ is a real NLS, $M$ is a linear manifold in $X$, and $p$ is a sublinear functional on $X$. Let $f_0$ be a linear functional on $M$ such that $f_0(x) \leq p(x)$, $z$ any vector in $X - M$, and $M_z = \{x + az : x \in M, \ a \in \mathbb{R}\}$. Then there exists a linear functional $f : M_z \to \mathbb{R}$ such that:

1. $f(x) = f_0(x)$ for all $x$ in $M$,
2. $f(x) \leq p(x)$ for all $x$ in $M_z$.

**Proof.**

(a) The representation of a vector $v = x + az \in M_z$ is unique. For if $x + az = v$, then $az = -x \in M$, hence $a = 0$, for otherwise $z = a^{-1}x \in M$. Thus if $x_1 + a_1z = x_2 + a_2z$, then $(x_1 - x_2) + (a_1 - a_2)z = 0$, which implies that $a_1 - a_2 = 0$ and $x_1 - x_2 = 0$.

(b) If $t \in f(z)$ and $f(x + az) = f_0(x) + at$ ($x \in M, \ a \in \mathbb{R}$), then $f$ is linear on $M_z$ and $f(x) = f_0(x)$ on $M$.

(c) Thus it suffices to choose $t$ so that $f_0(x) + at \leq p(x + az)$ for $x \in M$ and $a \in \mathbb{R}$ (i.e. $f \leq p$ on $M_z$). This is clearly satisfied if $a = 0$. If $a > 0$, the condition $*$ is equivalent to

$$f_0(a^{-1}x) + t \leq p(a^{-1}x + z),$$

and for $a < 0$ it is equivalent to

$$f_0(a^{-1}x) + t \geq -p(-a^{-1}x - z),$$

using the fact that $p$ is semihomogeneous. Thus it suffices to show that a fixed $t$ can be chosen so that

$$-p(-x-z) - f_0(x) \leq t \leq -f_0(y) + p(y + z) \text{ for all } x, y \text{ in } M.$$
(d) It suffices to show that \(-p(-x-z) - f_o(x) \leq -f_o(y) + p(y+z)\),
which is equivalent to \(f_o(y) - f_o(x) = f_o(y - x) \leq p(y + z) + p(-x - z)\).
But this is true by the subadditivity of \(p\), therefore

\[
t_o = \sup_{x \in M} [-p(-x - z) - f_o(x)] \leq \inf_{y \in M} [-f_o(y) + p(y+z)] = t_1,
\]
and any \(t \in [t_o, t_1]\) will do for \(f(z)\). This completes the proof of
the lemma.

Now let \(\mathcal{E}\) be the class of all linear extensions \(f : M_f \to \mathbb{R}\) of
\(f_o\) on linear manifolds \(M_f(M \subseteq M_f \subseteq X)\), such that \(f(x) \leq p(x)\) on \(M_f\).
Then \(\mathcal{E}\) is partially ordered by inclusion \(\subseteq\) if the functionals in \(\mathcal{E}\)
are considered as sets of ordered pairs. Let \(\zeta\) be any chain (linearly
ordered subclass) in \(\mathcal{E}\). Then \(g = \bigcup \{f : f \in \zeta\} \supseteq f\) for all \(f\) in
\(\zeta\), and \(g\) is a functional \(g : D \to \mathbb{R}\) with domain \(D \subseteq X\), such that
\(g(x) = f_o(x)\) on \(M\) and \(g(x) \leq p(x)\) on \(D\). Furthermore \(D\) is a
linear manifold, which means that \(g \in \mathcal{E}\). Therefore each chain \(\zeta\) in
\(\mathcal{E}\) has an upper bound, and by Zorn's lemma \(\mathcal{E}\) has a maximal element
\(f_1 : M_{f_1} \to \mathbb{R}\). Finally \(M_{f_1} = X\), for otherwise \(f_1\) could be extended
further by the lemma, which would contradict the maximality of \(f_1\).

Therefore, if \(X\) is a real linear space, \(p\) is a sublinear
functional on \(X\), \(M\) is a linear manifold in \(X\), and \(f_o\) is a linear
functional on \(M\) such that \(f_o(x) \leq p(x)\), then there is a linear func-
tional \(f : X \to \mathbb{R}\) such that

1. \(f(x) = f_o(x)\) for all \(x\) in \(M\),
2. \(f(x) \leq p(x)\) for all \(x\) in \(X\).

Now if \(p(x) = |f_o|^*|x|\), then \(p\) is clearly sublinear on \(X\),
and \(f_o(x) \leq |f_o(x)| \leq |f_o| |x| = p(x)\) for all \(x\) in \(M\). Hence there
exists a linear functional $f : X \rightarrow \mathbb{Z}$ such that $f(x) = f_o(x)$ on $M$ and $f(x) \geq |f_o| \cdot |x|$. Furthermore $f(-x) = -f(x) \leq |f_o| \cdot |-x| = |f_o| \cdot |x|$, hence $f(x) \geq -|f_o| \cdot |x|$. Therefore $|f(x)| \leq |f_o| \cdot |x|$ for all $x \in X$, which implies that $|f| \leq |f_o|$. But clearly $|f_o| \leq |f|$, hence $|f| = |f_o|$.

Suppose that $X$ is a complex NLS, $M$ is a manifold in $X$, and $f_o(x) = g_o(x) + ih_o(x)$ is a complex bounded linear functional on $M$. Then $f_o(ix) = g_o(ix) + ih_o(ix) = if_o(x) = ig_o(x) - h_o(x)$, hence $h_o(x) = -g_o(ix)$, and $f_o(x) = g_o(x) - ig_o(ix)$.

Now $g_o$ is a real linear functional on $M$, considering $X$ and $M$ as real linear spaces for the moment, and $|g_o(x)| \leq |f_o(x)|$ implies $|g_o| \leq |f_o|$. Therefore, by the real case, there is a bounded real linear functional $g$ on $X$ such that $g(x) = g_o(x)$ on $M$ and $|g| = |g_o| \leq |f_o|$. Define $f(x) = g(x) - ig(ix)$. Then clearly $f(x) = f_o(x)$ for all $x$ in $M$, $f$ is additive, and $f$ is real linear since $g$ is. But $f(ix) = g(ix) - ig(-x) = if(x)$, hence $f$ is complex linear.

To complete the proof it suffices to show that $|f| \leq |f_o|$. Write $f(x) = |f(x)|e^{i\alpha}$, where $\alpha = \arg f(x)$. Then

$$|f(x)| = e^{-i\alpha} f(x) = f(e^{-i\alpha} x) = g(e^{-i\alpha} x).$$

For all $x$ such that $|x| = 1$, $|e^{-i\alpha} x| = 1$, and

$$|f(x)| = g(e^{-i\alpha} x) \leq |g| = |g_o| \leq |f_o|.$$

This completes the proof of the Hahn-Banach Theorem.

**Corollary 1.** If $x_o$ is any vector in $X$, then there exists a bounded linear functional $f \in X'$ such that $f(x_o) = |x_o|$ and $|f| = 1$. 
Proof. Let $M = \{\alpha x_0 : \alpha \in \mathbb{Z}\}$. Then clearly $M$ is a linear manifold. Define the functional $f_0$ on $M$ by $f_0(\alpha x_0) = \alpha |x_0|$. Then $f_0$ is a bounded linear functional on $M$, and $|f(\alpha x_0)| = |\alpha x_0|$ implies that $|f_0| = 1$ unless $x_0 = \theta$. Thus the conclusion follows immediately from the Hahn-Banach theorem unless $x_0 = \theta$. If $x_0 = \theta$, then choose any nonzero vector $x_1$ and repeat the same argument with $x_0$ replaced by $x_1$. Thus there is a functional $f \in X'$ such that $f(\theta) = f(\theta) = 0 = |\theta|$ and $|f| = 1$.

Corollary 2. If $X$ is a separable NLS, then there is a countable set $[x_n] \subset X'$ such that $|x_n'| = 1$ and $|x| = \sup |x_n'x|$ for all $x \in X$.

(If $Z = \mathbb{R}$, then $|x| = \sup x_n'x$.)

Proof. Let $D = [x_n]$ be a countable dense subset of $X$. By Corollary 1, for each $n$ there is an $x_n' \in X'$ such that $|x_n'| = 1$ and $x_n'x_n = |x_n|$. Now let $x$ be any point in $X$, and let $\varepsilon > 0$. Choose $x_m$ so that $|x - x_m| < \varepsilon$. Then $|x| - |x_m| < \varepsilon$, and

$$|x_n'x_m| - |x_n'x| \leq |x_n'(x_m - x)| \leq |x_n'| |x_m - x| < \varepsilon,$$

so $|x_n'x| \geq |x_n'x_m| - \varepsilon = |x_m| - \varepsilon > |x| - 2\varepsilon$, which implies that $\sup |x_n'x| \geq |x|$. But clearly $\sup |x_n'x| \leq |x|$, since

$$|x_n'x| \leq |x_n'| |x| = |x|$$

for all $n$.

It follows easily from Corollary 2 that if $X$ is a separable Banach space and $X : \Omega \rightarrow X$ is Bochner summable, then $\int_X = 0$ for all $a \in \mathscr{A}$ implies $X^{a} = \mathbb{S} \cdot \theta$. First note that if $x' \in X'$, then
\[ x' \int X = \int x'^X \] for simple functions, hence also for summable functions since \( x' \) is continuous. If \( \left\{ x'_n \right\} \) if the set of functionals in Corollary 2, then \( \int_A X = 0 \) for all \( A \in \mathcal{A} \) implies \( x'_n \int A = \int_A x'_n X = 0 \). Hence \( x'_n X = 0 \) for each \( n \) by the scalar case, and then
\[
|X| = \sup |x'_n X| = 0
\]
by Corollary 2, which implies that \( X = 0 \).

**Corollary 3.** Suppose \( M \) is a linear manifold in \( X \), \( x \in M^\perp = M^\prime \), and \( \delta = d(x, M) = \inf |x - y| \). Then there exists \( x' \in X^\prime \) such that \( x'M = [0] \), \( x'x = \delta \), and \( |x'| = 1 \). For the proof see HILLE and PHILLIPS p. 30.

The conjugate space of \( X^\prime \) is denoted by \( X'' \), and is called the second conjugate space of \( X \). Thus \( X'' \) is the set of all bounded linear functionals \( x'' : X^\prime \to \mathbb{Z} \); it will be important in the considerations of this paper, inasmuch as it is used to define the weak topology on \( X \) to be denoted by \( \mathcal{W} \). It is shown below that the original space \( X \) is always isometrically isomorphic to a subspace of \( X'' \).

For each pair \( x \in X \), \( x' \in X^\prime \), let \( f(x, x') = F_x(x') = x'x \). If \( x' \) is held fixed and \( x \) is allowed to vary, this expression defines the functional \( x' : X \to \mathbb{Z} \). On the other hand, \( x \) may be held fixed and \( x' \) allowed to vary; then \( F_x(x') = x'x \) is a scalar for each \( x' \in X^\prime \), and thus defines a functional \( F_x : X^\prime \to \mathbb{Z} \). This functional \( F_x \) is actually an element of \( X'' \), since
\[
F_x(ax' + \beta y') = (ax' + \beta y')x = a(x'x) + \beta (y'x) = aF_x(x) + \beta F_x(y'),
\]
and \( |F_x'(x)| = |x'x| \leq |x'|-|x| = |x||x'| \); clearly \( |F_x| \leq |x| \).

Thus to each point \( x \) in \( X \) there is associated a point \( F_x \) in \( X'' \) by the mapping \( F : X \rightarrow X'' \), called the canonical mapping; where for each \( x \) in \( X \), its image \( F_x : X' \rightarrow E' \) under the canonical mapping is defined by

\[
F_x(x') = x' \quad \text{for } x' \in X'.
\]

Clearly the canonical mapping is a homomorphism, \( (F_{x} + F_{y})(x') = F_x(x') + F_y(x') \), since

\[
F_{x}(x')(x') = x'(ax + by) = ax'x + bx'y = aF_{x}(x') + bF_{y}(x').
\]

= \( (aF_{x} + bF_{y})(x') \). Thus it remains to show that \( F \) is 1-1 and isometric.

Since \( F \) is linear, to show that \( F \) is 1-1 (\( F_x = F_y \Rightarrow x = y \)) it suffices to show that \( F_x = 0^n \Rightarrow x = 0 \), where \( 0 \) and \( 0^n \) are the origins (zero vectors) in \( X \) and \( X'' \) respectively. Suppose \( x_0 \in X \) and \( F_{x_0} = 0^n \). This means that \( F_{x_0}(x') = x'x_0 = 0 \) for all \( x' \in X' \). For each \( x \in X \), by the first corollary of the Hahn-Banach theorem there is a functional \( x' \in X' \) such that \( |x'| = 1 \) and \( x'x = |F_{x}x'| \leq |F_{x}| \). Therefore

\[
F_{x_0} = 0^n \Rightarrow x'x_0 = |x_0| = 0 \Rightarrow x_0 = 0.
\]

Notice also that given \( x \in X \), there exists \( x' \in X' \) such that \( |x'| = 1 \) and \( |x| = x'x = |F_{x}x'| \leq |F_{x}| \). Therefore \( |x| = |F_{x}| \) for all \( x \in X \), since it was shown above that \( |F_{x}| \leq |x| \). A NLS \( X \) is reflexive if and only if \( FX = X'' \). Clearly \( X \) must be a Banach space if it is reflexive, since \( X'' \) is a Banach space.

**Extended Hahn-Banach Theorem.** Let \( X \) be a NLS, \( M \) a linear manifold in \( X \), \( Y \) a reflexive, separable Banach space, and \( F_0 : M \rightarrow Y \) a bounded linear transformation. Then there exists a bounded linear transformation \( F : X \rightarrow Y \) such that
(1) $F_x = F_0 x$ for all $x$ in $M$

(2) $|F| = |F_0|.$

Proof. For each $y' \in \mathcal{V}'$, $y'F_0 \in M'$, since

$$y'F_0(ax) = ay'(F_0 x), \quad y'F_0(x_1 + x_2) = y'(F_0 x_1 + F_0 x_2) = y'F_0 x_1 + y'F_0 x_2,$$

and $|y'F_0(x)| \leq |y'| |F_0| |x|.$

Therefore, by the Hahn-Banach Theorem, $y'F_0$ can be extended to a bounded linear functional $x' \in X'$ such that $|x'| = |y'F_0|$, where $x' = x'(y')$. (Note that $x'(\theta') = \theta' \cdot \theta.$) Now define $F : X \to Y$ by the requirement that, for all $y' \in \mathcal{Y}'$, $y'F(x) = x'x$, where $x' = x'(y')$.

Note that the functionals $x' = x(y')$ are considered as fixed, once they have been chosen. Having fixed them, the equation $y'F(x) = x'x$ (where $x' = x'(y')$) determines $F(x) = y$ uniquely if it exists. For if $y'y_1 = y'y_2 = x'x$ for all $y'$ in $\mathcal{V}'$, then $y_1 = y_2$. (As $y'$ varies, so does $x'$, but $x$ is fixed here.)

The question arises, however, as to whether $y$ even exists so that $y'y = x'x$ for all $y'$ in $\mathcal{V}'$, where $x$ is fixed and $x' = x'(y')$. That is, given $x$ in $X$ and $y'$ in $\mathcal{Y}'$ (which determines $x' = x'(y')$ in $X'$), $y$ in $Y$ must be chosen so that $y'y = x'x$.

If $y' = \theta'$, then $x' = \theta', \quad \text{and there is nothing to prove. Otherwise,}$

by the Hahn-Banach Theorem (Corollary 1) there exists $y''$ in $\mathcal{V}''$ such that $y''y' = 1$. Then $(x'x)y'' \in \mathcal{V}''$ and $(x'x)y''y' = x'x$. But since $Y$ is reflexive, there exists $y \in Y$ such that $[(x'x)y'']y = y'y = x'x$.

Thus $y = F(x)$ is determined by

$$y'F(x) = x'x, \quad y' \in \mathcal{V}'.
Suppose \( x \in M \). By the definition of \( x' \), \( y' F_o(x) = x' x \) for \( x \) in \( M \), hence

\[ F(x) = F_o(x) \quad \text{for all} \quad x \in M. \]

Since \( y' F(x_1 + x_2) = x'(x_1 + x_2) = x' x_1 + x' x_2 = y' F(x_1) + y' F(x_2) \)

\[ = y' (F x_1 + F x_2) \quad \text{for all} \quad y' \in Y', \]

\( F(x_1 + x_2) = F(x_1) + F(x_2); \) similarly \( F(\alpha x) = \alpha F(x) \).

It remains to show that \( |F| \leq |F_o| \). It suffices to show that \( |F x| \leq |F_o| \) for \( |x| = 1 \). Recall that for \( |x| = 1 \),

\[ |x' x| = |y' F(x)| \leq |x'| = |y' F_o| = \sup_{|x| = 1, \, x \in M} |y' F_o(x)| \]

for each \( y' \) in \( Y' \).

Since \( Y \) is separable, there exists a countable set

\[ \left\{ y_n' \right\} \subset Y' \] such that \( |y| = \sup |y_n' y| \).

For \( |x| = 1 \) and each \( n \),

\[ |y_n' F(x)| \leq \sup \left| y_n' F_o(x) \right| = \sup \left\{ \sup_{|x| = 1, \, x \in M} |y_n' F_o(x)| \right\} = \sup_{n} |F_o x| = |F_o|, \]

Therefore \( |F(x)| = \sup_n |y_n' F(x)| \leq |F_o| \), which completes the proof.

**Topology.** Let \( X \) be a topological space. A class \( \mathcal{J} \) is a subbase for the topology \( \mathcal{U} \) iff the class \( \mathcal{J} = \left\{ \bigcap_{k=1}^{n} S_k : S_k \in \mathcal{J}; n = 1, 2, 3, \ldots \right\} \) of all finite intersections of \( \mathcal{J} \)-sets is a base for \( \mathcal{U} \). Every class \( \mathcal{J} \) such that \( \bigcup \mathcal{J} = X \) is a subbase for a topology \( \mathcal{U} \) on \( X \), since every
\( \mathcal{J}_x = [T : x \in T \in \mathcal{U}] \) is a nonempty class of nonempty sets which is closed under finite intersection, and hence every \( \mathcal{J}_x \) is a direction. This topology \( \mathcal{U} \) generated by \( \mathcal{J} \) is clearly the smallest topology on \( X \) containing \( \mathcal{J} \), since \( \mathcal{U} \subset \mathcal{V} \) for every topology \( \mathcal{V} \) on \( X \) such that \( \mathcal{J} \subset \mathcal{V} \). That is \( \mathcal{U} = \mathcal{J} \), where

\[
\mathcal{J} = \bigcap \{ \mathcal{V} : \mathcal{V} \text{ is a topology, } \mathcal{J} \subset \mathcal{V} \}.
\]

Conversely, if \( \mathcal{U} = \mathcal{J} \), then \( \mathcal{J} \) is a subbase for \( \mathcal{U} \). For otherwise the topology \( \mathcal{U}(\mathcal{J}) \) consisting of all unions of finite intersections of \( \mathcal{J} \)-sets is a topology on \( X \) containing \( \mathcal{J} \) such that \( \mathcal{U} \setminus \mathcal{U}(\mathcal{J}) \neq \emptyset \), which contradicts \( \mathcal{U} = \mathcal{J} \subset \mathcal{U}(\mathcal{J}) \).

Thus if \( \bigcup \mathcal{J} = X \), then \( \mathcal{U} = \mathcal{J} \) iff \( \mathcal{J} \) is a subbase for \( \mathcal{U} \). It follows from the definition that \( \mathcal{J} \subset \mathcal{J}' \), \( \mathcal{J} = \mathcal{J}' \), \( \mathcal{A} \subset \mathcal{J} \supset \mathcal{A} \subset \mathcal{J}' \), \( \mathcal{A}' \subset \mathcal{J}' \), and \( (\mathcal{A} \cup \mathcal{J})^{-} = (\mathcal{A} \cup \mathcal{J}')^{-} \). Thus the operation \( (\cdot)^{-} \) of taking minimal topologies containing classes \( \mathcal{J} \) with \( \bigcup \mathcal{J} = X \) is analogous to the operation \( (\cdot)^{-} \) of taking closures of sets \( A \); except that \( (A \cup B)^{-} = \overline{A} \cup \overline{B} \), while in general \( (\mathcal{A} \cup \mathcal{J})^{-} \neq \overline{\mathcal{A}} \cup \overline{\mathcal{J}} \), since unions of topologies are not in general topologies.

Let \( (X_t, \mathcal{U}_t, \mathcal{B}_t) \) be a family of topological measurable (T.M.) spaces and \( f_t : X_o \rightarrow X_t \), \( t \in T \), a family of functions, where \( X_o \) is an arbitrary nonempty set. Recall that \( \mathcal{U}_0 = f_t^{-1} \mathcal{U}_t \) is the smallest topology on \( X_o \) such that \( f_t \) is \( (\mathcal{U}_0, \mathcal{U}_t) \) continuous, and \( \mathcal{B}_0 = f_t^{-1} \mathcal{B}_t \) is the smallest \( \sigma \)-field on \( X_o \) such that \( f_t \) is \( (\mathcal{B}_0, \mathcal{B}_t) \) measurable, for each \( t \in T \). Let \( \mathcal{J}_o = \bigcup_{t \in T} f_t^{-1} \mathcal{U}_t \) and \( \mathcal{B}_o = \bigcup_{t \in T} f_t^{-1} \mathcal{B}_t \). Then clearly \( \mathcal{U}_0 = \mathcal{J}_o \) is the smallest topology on \( X_o \).
such that \( f_t \) is \((\mathcal{U}_t, \mathcal{G}_t)\) continuous for all \( t \in T \), and \( \mathcal{G}_o = \mathcal{G}_o \)
is the smallest \( \sigma \)-field on \( X_o \) such that \( f_t \) is \((\mathcal{G}_o, \mathcal{G}_t)\) measurable
for all \( t \in T \). If \( \mathcal{U}_t \) and \( \mathcal{G}_t \) are replaced by \( \mathcal{F}_t \) and \( \mathcal{Q}_t \) respectively
in the definitions of \( \mathcal{F}_o \) and \( \mathcal{Q}_o \) above, where \( \mathcal{F}_t = \mathcal{U}_t \) and \( \mathcal{Q}_t = \mathcal{G}_t \),
then \( \mathcal{U}_o \) and \( \mathcal{Q}_o \) remain the same as before.

The topology \( \mathcal{U}_o = \mathcal{F}_o = \left( \bigcup_{t \in T} \mathcal{U}_o \right) \) is called the \textit{compound topology}
of the topologies \( \mathcal{U}_o \), and the \( \sigma \)-field \( \mathcal{G}_o = \mathcal{Q}_o = \left( \bigcup_{t \in T} \mathcal{G}_o \right) \) is called
the \textit{compound \( \sigma \)-field} of the \( \sigma \)-fields \( \mathcal{G}_o \).

The same situation can also be considered from a slightly differ-
ent viewpoint. Namely consider the product space \( X = \prod_{t \in T} X_t \), and
recall that the projection mappings \( p_t : X \to X_t \) are defined by
\( p_t x = x_t \) for each \( x = (x_t : t \in T) \in X \). The family of functions \( f_t \)
can be considered as a function
\[
f = (f_t : t \in T) : X_o \to X
\]
with component functions \( f_t \), and then
\[
f_t = p_t f, \quad t \in T.
\]

It would therefore be desirable to put a topology \( \mathcal{U} \) and a
\( \sigma \)-field \( \mathcal{G} \) on \( X \) which are small enough so that \( f : X_o \to X \) is
\((\mathcal{U}_o, \mathcal{U})\) continuous and \((\mathcal{G}_o, \mathcal{G})\) measurable, and large enough so that
each projection \( p_t : X \to X_t \) is \((\mathcal{U}, \mathcal{U}_t)\) continuous and \((\mathcal{G}, \mathcal{G}_t)\)
measurable. This is always possible; in fact the projections \( p_t \) will
be \((\mathcal{U}, \mathcal{U}_t)\) continuous and \((\mathcal{G}, \mathcal{G}_t)\) measurable if \( \mathcal{U} \) and \( \mathcal{G} \) are
respectively the compound topology and compound \( \sigma \)-field on \( X \) generated
by the projections, replacing \( X_o \) by \( X \) and \( f_t \) by \( p_t \) in the
previous discussion.

Thus $\mathcal{U} = \mathcal{I}$, where $\mathcal{I} = \bigcup_{t \in T} p_t^{-1} \mathcal{U}_t$, and $\mathcal{B} = \mathcal{G}$, where $\mathcal{G} = \bigcup_{t \in T} p_t^{-1} \mathcal{U}_t$. But clearly $f^{-1}(p_t^{-1} \mathcal{U}_t) = f_t^{-1} \mathcal{U}_t \in \mathcal{U}_o$ for each $\mathcal{U}_t \in \mathcal{U}_t$, and $f^{-1}(p_t^{-1} \mathcal{B}_t) = f_t^{-1} \mathcal{B}_t \in \mathcal{B}_o$ for each $\mathcal{B}_t \in \mathcal{B}_t$, by definition of $\mathcal{U}_o$ and $\mathcal{B}_o$. Hence $f^{-1} \mathcal{I} \subseteq \mathcal{U}_o$ and $f^{-1} \mathcal{G} \subseteq \mathcal{B}_o$, which implies that $f^{-1} \mathcal{I} \subseteq \mathcal{U}_o$ and $f^{-1} \mathcal{G} \subseteq \mathcal{B}_o$, as desired.

The topology $\mathcal{U}$ is called the product topology on $X$, and the $\sigma$-field $\mathcal{B}$ is called the product $\sigma$-field on $X$.

If $(\Omega, \mathcal{I}, \mathcal{A})$ is a given T.M. space and $X : \Omega \rightarrow X$, then it follows from the definitions that $X$ is $(\mathcal{I}, \mathcal{U})$-continuous or $(\mathcal{A}, \mathcal{B})$-measurable iff $X_t$ is $(\mathcal{I}_t, \mathcal{U}_t)$-continuous or $(\mathcal{A}_t, \mathcal{B}_t)$-measurable, respectively, for each $t \in T$.

Suppose $(X, \mathcal{U})$ is a top. space, $\mathcal{I}$ is a base for $\mathcal{U}$, $\mathcal{I}_Y$ is a subbase for $\mathcal{U}_Y$, $Y \subseteq X$, and $\mathcal{V} = \mathcal{U}_Y = \{ U_Y : U \in \mathcal{U} \}$. It follows that $(Y, \mathcal{V})$ is a topological space, called a subspace of $(X, \mathcal{U})$, and that $\mathcal{I}_Y$ is a base for $\mathcal{U}_Y$ and $\mathcal{I}_Y$ is a subbase for $\mathcal{U}_Y$. Furthermore

$$\mathcal{V}^C = \{ Y - V : V \in \mathcal{V} \} = \mathcal{U}_Y^C,$$

and if $B \subseteq Y$ then $B^{-} = B^{-} Y$, where $B^{-} Y$ is the closure of $B$ with respect to $\mathcal{V}$. The topology $\mathcal{V}$ is called the relative topology, or the relativization of $\mathcal{U}$ on $Y$.

A top. space $X$ is compact $(K_2)$ iff every open cover of $X$ has a finite subcover; note that every $K_2$ space is $L_1 \ (K_2 \subseteq L_1)$. A subset $A \subseteq X$ is compact iff it is compact in its relative topology; equivalently iff every open cover of $A$ has a finite subcover. It follows easily that every closed subset of a compact space is compact.
Alexander Subbase Theorem. Let \((X, \mathcal{U})\) be a top. space, and suppose \(\mathcal{B}\) is a subbase for \(\mathcal{U}\). Then \(X\) is compact iff every open cover \(\zeta \subset \mathcal{B}\) has a finite subcover.

Proof. Let \(A = [\zeta \subset \mathcal{U}: \zeta \text{ covers } X]\), \(F = [\zeta \subset \mathcal{U}: \text{some finite subclass of } \zeta \text{ covers } X]\), \(A' = [\zeta \subset \mathcal{U}: \zeta \text{ does not cover } X]\), and \(F' = [\zeta \subset \mathcal{U}: \text{no finite subclass of } \zeta \text{ covers } X]\).

Then \(X\) is compact iff \(A \subset F\), or equivalently \(F' \subset A'\). Classes \(\zeta\) in \(A\), \(F\), \(A'\), and \(F'\) are called adequate, finitely adequate, inadequate, and finitely inadequate respectively. The plan of the proof is to show that if every finitely inadequate class of subbase sets is inadequate, then every finitely inadequate class is inadequate; symbolically,

\[
F' \subset A' \supset F' \subset A' .
\]

Consider a fixed finitely inadequate class \(\emptyset \in F'\), and let \(F'_{\emptyset} = [\zeta \in F': \emptyset \subset \zeta]\). To show that \(\emptyset\) is inadequate, it suffices to show that \(F'_{\emptyset}\) has a maximal finitely inadequate class \(M \supset \emptyset\), and that \(M\) is inadequate. Let \(F'_{\emptyset}\) be partially ordered by inclusion \(\subset\), and let \(\mathcal{C}\) be a linearly ordered subfamily (chain) of \(F'\). Then \(\mathcal{C}\) has an upper bound in \(F'_{\emptyset}\); namely \(\zeta^* = \bigcup [\zeta: \zeta \in \mathcal{C}]\). To see this, it suffices to show that \(\zeta^* \in F'_{\emptyset}\). If this is false, there is a finite subclass \([C_1, \ldots, C_n]\) of \(\zeta^*\) which covers \(X\), where \(C_k \in \zeta_k \in \mathcal{C}\). Then \(\zeta = \bigcup_{1}^{n} \zeta_k \in F\), and \(\zeta \in \mathcal{C}\) since \(\mathcal{C}\) is linearly ordered, which is a contradiction. Therefore every chain in \(F'_{\emptyset}\) has an upper bound, and by
Zorn's lemma $E^*_G$ has a maximal class $m = m_G$. Note that $m$ is also a maximal class in $E'$, and $\emptyset \in m$ since $m$ is maximal.

Since $m \in E'$, clearly $\emptyset \cap m = [S : S \in \emptyset, S \in m] \in E'$, hence $\emptyset \cap m \in A'$ by hypothesis. Therefore, to show that $m \in A'$, it suffices to show that

$$\bigcup \{M : M \in m\} \subset \bigcup \{S : S \in \emptyset \cap m\} \neq X.$$

Let $x \in M \in m$. Then by definition of subbase, there exist sets $S_j \in \emptyset$ $(j = 1, \ldots, m)$ such that

$$x \in \bigcap_{1}^{m} S_j \subseteq M.$$

Therefore it suffices to show that $S_j \in m$ for some $j$, for then $x \in S_j \subseteq \bigcup \{S : S \in \emptyset \cap m\}$. Suppose this is false, so that $S_j \notin m$ for $j = 1, \ldots, m$. Then $M_j = m + [S_j] \in E$ for each $j = 1, \ldots, m$ by the maximality of $m$; thus for each $j$ there is a finite subclass $[M_{jk} : k = 1, \ldots, n_j] \subset m$ such that

$$S_j \cup M_{j1} \cup \ldots \cup M_{jn_j} = X.$$

Now for each $j$, $S_j = \bigcap_{i=1}^{m} S_i + \bigcup_{i=1}^{m} (S_j - S_i)$, and $S_j - S_i \subseteq S_i \cup M_{i1} \cup \ldots \cup M_{in_i}$. It follows that

$$\bigcup_{j=1}^{m} S_j \cup M_{j1} \cup \ldots \cup M_{jn_j} = \left(\bigcap_{i=1}^{m} S_i\right) \cup \left(\bigcup_{j=1}^{m} \bigcup_{k=1}^{n_j} M_{jk}\right) = X.$$

But since $\bigcap_{i=1}^{m} S_i \subseteq m \in m$, this implies that $m \in A$, which is a contradiction. Thus the proof is complete.
Tychonov. Product Theorem. If \((X_t, \mathcal{U}_t), \ t \in T,\) is any family of compact top. spaces, then the product space \((X^T, \mathcal{U}^T)\) is compact.

**Proof.** Let \(\mathcal{G}^T = \{p_t^{-1}U_t : U_t \in \mathcal{U}_t, \ t \in T\}\) be the usual subbase for the product topology \(\mathcal{U}^T,\) and let \(\zeta\) be any finitely inadequate class of subbase sets. According to the Alexander Subbase Theorem, it suffices to show that \(\zeta\) is inadequate.

For each \(t \in T,\) let \(\zeta_t = \{u_t \in \mathcal{U}_t : p_t^{-1}U_t \in \zeta\}.\) Clearly each \(\zeta_t\) is finitely inadequate for \(X_t;\) hence also inadequate, since each \(X_t\) is compact. Therefore, for each \(t \in T,\) there exists a point \(x_t\) such that \(x_t \notin U_t\) for all \(U_t \in \zeta_t.\) Thus if \(x = (x_t : t \in T),\) then \(x \notin p_t^{-1}U_t\) for all \(p_t^{-1}U_t \in \zeta,\) which means that \(\zeta\) is inadequate.

If \(X\) is a NLS, then \(X' \subseteq \Pi \mathcal{Z}_x,\) where \(\mathcal{Z}_x = \mathcal{Z}\) for all \(x.\)

Thus it would seem that another natural topology on \(X'\) is the relativized product topology. It will be seen later that this topology, which is denoted by \(\mathcal{U}'\) and called the weak* topology, does indeed turn out to be useful.

Recall that the usual subbase for the product topology \(\mathcal{U}^X\) on \(\mathcal{Z}^X\) is

\[
\mathcal{G}^X = \bigcup_{\mathcal{S} \in J} \{[f \in \mathcal{Z}^X : f_x \in \mathcal{S}]\}
\]

where \(J\) is any subbase for the topology \(\mathcal{U}\) on \(\mathcal{Z}.\) It will be convenient to take for \(J\) the usual base for \(\mathcal{U};\) namely the class of all \(\varepsilon\-)neighborhoods. We could of course let \(J\) be the usual countable base consisting of all \(\varepsilon\-)nhds. with rational centers and rational radii, but this is no help; the weak* topology is not in general second
countable, or even first countable, unless $X$ is finite dimensional.

Thus the corresponding subbase for the weak topology $\mathcal{W}'$ is

$$\mathcal{S}' = \bigcup_{\varepsilon > 0, \lambda \in \mathbb{Z}} \{[x' \in X' : |x' - \lambda| < \varepsilon] \}$$

and the sets

$$W_{x_0}^{x'} = \bigcap_{k=1}^{n} [x' \in X' : |x_k - x_0| < \varepsilon]$$

form a base for the nhd. system of a point $x_0 \in X'$.

\textit{\(\mathcal{W}'\)-Compactness Theorem.} The unit ball $B_1^1 = [x' : |x'| \leq 1]$ is always $\mathcal{W}'$ compact.

\textbf{Proof.} Since $|x'x| \leq |x'x| \leq |x|$ for all $x' \in B_1^1$,

$$B_1^1 = [x' : |x'| \leq 1] \subset \prod_{x \in X} [a \in \mathbb{Z}_x : |a| \leq |x|] (\mathbb{Z}_x = \mathbb{Z} \text{ for all } x)$$

But $\prod_{x \in X} [a \in \mathbb{Z}_x : |a| \leq |x|]$ is compact in its relativized product topology (hence in the product topology on $\mathbb{Z}^X$) by the Tychonov Product Theorem, since $[a \in \mathbb{Z} : |a| \leq |x|]$ is a compact subset of $\mathbb{Z}$ for each $x \in X$. Note here that the product topology on $\prod_{x \in X} [a \in \mathbb{Z}_x : |a| \leq |x|]$ is the same as the relativized product topology. Since a closed subset of a compact set is compact, it therefore suffices to show that $B_1^1$ is $\mathcal{W}'$ closed.

Let $g \in \overline{B_1^1}$, the closure of $B_1^1$ in the product topology of $\mathbb{Z}^X$. It is not clear that $g$ is even in $X'$, much less in $B_1^1$; this is what must be shown. Choose any $\varepsilon > 0$, and let $x$ and $y$ be any two points in $X$ and $a$ any scalar. Let

$$\mathcal{S}' = \bigcup_{\varepsilon > 0, \lambda \in \mathbb{Z}} \{[x' \in X' : |x' - \lambda| < \varepsilon] \}$$

and the sets

$$W_{x_0}^{x'} = \bigcap_{k=1}^{n} [x' \in X' : |x_k - x_0| < \varepsilon]$$

form a base for the nhd. system of a point $x_0 \in X'$.

\textit{\(\mathcal{W}'\)-Compactness Theorem.} The unit ball $B_1^1 = [x' : |x'| \leq 1]$ is always $\mathcal{W}'$ compact.

\textbf{Proof.} Since $|x'x| \leq |x'x| \leq |x|$ for all $x' \in B_1^1$,

$$B_1^1 = [x' : |x'| \leq 1] \subset \prod_{x \in X} [a \in \mathbb{Z}_x : |a| \leq |x|] (\mathbb{Z}_x = \mathbb{Z} \text{ for all } x)$$

But $\prod_{x \in X} [a \in \mathbb{Z}_x : |a| \leq |x|]$ is compact in its relativized product topology (hence in the product topology on $\mathbb{Z}^X$) by the Tychonov Product Theorem, since $[a \in \mathbb{Z} : |a| \leq |x|]$ is a compact subset of $\mathbb{Z}$ for each $x \in X$. Note here that the product topology on $\prod_{x \in X} [a \in \mathbb{Z}_x : |a| \leq |x|]$ is the same as the relativized product topology. Since a closed subset of a compact set is compact, it therefore suffices to show that $B_1^1$ is $\mathcal{W}'$ closed.

Let $g \in \overline{B_1^1}$, the closure of $B_1^1$ in the product topology of $\mathbb{Z}^X$. It is not clear that $g$ is even in $X'$, much less in $B_1^1$; this is what must be shown. Choose any $\varepsilon > 0$, and let $x$ and $y$ be any two points in $X$ and $a$ any scalar. Let

\begin{align*}
\mathcal{S}' &= \bigcup_{\varepsilon > 0, \lambda \in \mathbb{Z}} \{[x' \in X' : |x' - \lambda| < \varepsilon] \} \\
W_{x_0}^{x'} &= \bigcap_{k=1}^{n} [x' \in X' : |x_k - x_0| < \varepsilon]
\end{align*}
\[ U_{g, \varepsilon} = \{ f : X \to Z ; |f(x) - g(x)| < \varepsilon, |f(y) - g(y)| < \varepsilon, |f(x+y) - g(x+y)| < \varepsilon, \]
\[ \text{and } |f(ax) - g(ax)| < \varepsilon \} \]

Then \( U_{g, \varepsilon} \) is a neighborhood of \( g \); therefore, since \( g \in B_{1}^{\varepsilon} \), \( U_{g, \varepsilon} \) contains some \( f \in B_{1}^{\varepsilon} \). Note that \( f(x+y) = f(x) + f(y) \), \( f(ax) = af(x) \), and \( |f(x)| \leq |x| \). Hence,

\[ |g(x) + g(y) - g(x+y)| \leq |g(x) - f(x)| + |g(y) - f(y)| + |f(x+y) - g(x+y)| < 3\varepsilon, \]
\[ |ag(x) - g(ax)| \leq |ag(x) - af(x)| + |f(ax) - g(ax)| < (|a| + 1)\varepsilon, \text{ and} \]
\[ |g(x)| \leq |g(x) - f(x)| + |f(x)| < \varepsilon + |x|. \]

Since \( \varepsilon > 0 \) is arbitrary, it follows that \( g(x+y) = g(x) + g(y) \), \( g(ax) = ag(x) \), and \( |g(x)| \leq |x| (|g| \leq 1) \), so that \( g \in B_{1}^{\varepsilon} \). Thus \( B_{1}^{\varepsilon} \) is closed, and the proof is complete.

The canonical mapping \( F : X \to X'' \), defined by \( F_x(x') = x' x \), is an isometric isomorphism of \( X \) onto a subspace of \( X'' \), namely the subspace consisting of all bounded linear functions \( x'' : X' \to Z \) which are of the form \( x''x' = x' x \) for some \( x \) in \( X \). If \( X \) is only a NLS (not complete), then "subspace" should be replaced by "manifold."

The space \( X \) is said to be reflexive iff \( F_X = X'' \). Examples of reflexive spaces are the scalar Lebesgue spaces \( L^p_\mu \) \((1 < p < \infty, \mu \text{ } \sigma\text{-finite}) \) and Hilbert space \( H \).

It is sometimes convenient to identify \( X \) with its image \( F_X \) under the canonical mapping, since in this way \( X \) can be considered as a subspace of the function space \( X'' = (X')' \), which is in turn a subspace of the space \( 2^X \) of all scalar valued functions on \( X' \). Thus,
\[ X = FX \subset X'' = (X')^* \subset Z^{X'} = \prod_{x' \in X'} Z_x' \]

One should realize here that \( X \) and \( FX \) are not really "equal" in the usual sense, but since they are isometrically isomorphic it will do no harm to identify them. In fact this identification makes it possible to introduce a new topology on \( X \), namely the relativized product topology of \( Z^{X'} \), called the weak topology on \( X \) and denoted by \( \mathcal{W} \).

As before, the usual subbase for the product topology \( \mathcal{U}^{X''} \) on \( Z^{X'} \) is

\[ \mathcal{S}^{X'} = \bigcup_{\mathcal{S} \in \mathcal{J}, x' \in X'} \left\{ \left[ f \in Z^{X'} : f_{x'} \in \mathcal{S} \right] \right\}, \]

where \( \mathcal{J} \) is the class of all \( \varepsilon \)-neighborhoods in \( Z \).

Thus the subbase for the relativized product topology on \( X'' \) is

\[ \mathcal{S}'' = \bigcup_{\varepsilon > 0, \lambda \in Z} \left\{ \left[ x'' \in X'' : |x'' - x'| \varepsilon \lambda \right] \varepsilon \varepsilon \right\}, \]

and the subbase for the relativized product topology \( \mathcal{U} \) on \( X \) is

\[ \mathcal{S} = \bigcup_{\varepsilon > 0, \lambda \in Z} \left\{ \left[ x \in X : |x - x'| \varepsilon \lambda \right] \varepsilon \varepsilon \right\}. \]

The base neighborhoods are finite intersections of subbase neighborhoods, and the class of all sets of the form
\[ \mathcal{W}_x = \bigcap_{k=1}^{n} \{ x \in X : |x_k x - x'_k x_0| < \varepsilon \} \]

is a base for the nhd. system of the point \( x_0 \).

It should be noted that, in constructing the weak topology \( \mathcal{W} \), each element \( x \) in \( X \) can be thought of as a functional \( x : X' \to \mathbb{R} \) (actually the functional \( F_x' \) where \( F_x'(x') = x' x \)), and each element \( x' \) in \( X' \) can be thought of as a point. However, now that the weak topology has been constructed, one is free to reverse this and again think of elements \( x \) in \( X \) as points and elements \( x' \) in \( X' \) as functionals \( x' : X \to \mathbb{R} \). With this interpretation it is clear, from the definition of base neighborhoods of a point \( x_0 \) above that the weak topology \( \mathcal{W} \) is the smallest topology on \( X \) with respect to which all bounded linear functionals \( x' : X \to \mathbb{R} \) are continuous. In retrospect, it is equally clear from the definition that the \( \mathcal{V}' \) topology is the smallest topology on \( X' \) with respect to which all bounded linear functionals \( x : X' \to \mathbb{R} \) (actually \( F_x : X' \to \mathbb{R} \) where \( F_x(x') = x' x \)) are continuous.

**Weak Compactness Theorem.** If \( X \) is a reflexive Banach space, then the unit ball \( B_1 = \{ x : |x| \leq 1 \} \) is weakly compact.

**Proof.** By the \( \mathcal{W}' \) Compactness Theorem the unit ball \( B'' = \{ x'' : |x''| \leq 1 \} \) is compact with respect to the topology \( \mathcal{W}'' \), where \( \mathcal{W}'' \) is the weak * topology on \( X'' \). The topology \( \mathcal{W}'' \) is generated by the subbase

\[ \mathcal{G}'' = \bigcup_{\varepsilon > 0, \lambda, \varepsilon \in \mathbb{R}} \{ [x'' : |x'' x' - \lambda| < \varepsilon] \} . \]
But recall that the weak topology $\mathcal{W}$ on $X$ is generated by the subbase

$$\mathcal{G}'' = \bigcup_{\varepsilon > 0, \lambda \in \mathbb{Z}} \{[x' : |x'x - \lambda| < \varepsilon] \}$$

Therefore, since $X$ is reflexive, the topological spaces $(X, \mathcal{W})$ and $(X'', \mathcal{W}'')$ are clearly homeomorphic; the canonical mapping $F : X \rightarrow X''$ is a homeomorphism with respect to the weak topologies $\mathcal{W}, \mathcal{W}''$ as well as the strong topologies $\mathcal{U}, \mathcal{U}''$. Hence $B_1 = F^{-1}B_1''$ is compact.

It should be noted that the converse of this theorem is also true, so that a Banach space is reflexive if and only if the unit ball is weakly compact. For the proof see TAYLOR.

It was stated in the preceding two chapters that if $X$ is a separable Banach space, then every weakly measurable function $X : \Omega \rightarrow X$ is $(\mathcal{A}, \mathcal{U})$ measurable; this fact can now be proved with the aid of the Hahn Banach Theorem. If $\mathcal{J}$ is the class of all $\varepsilon$-nhd.'s in $X$ and $\mathcal{G} = \bigcup_{f \in X'} f^{-1}\mathcal{J}$ is the usual subbase for the weak topology $\mathcal{U}$, then $X$ is weakly measurable iff $X^{-1}\mathcal{G} = \bigcup_{f \in X'} (fX)^{-1}\mathcal{J} \subseteq \mathcal{A}$. Now since $X$ is separable, $\mathcal{W} = \mathcal{G}$ using the Lindelöf Theorem; therefore $X$ is weakly measurable iff it is $(\mathcal{A}, \mathcal{W})$ measurable. It will be shown below that every strongly closed sphere is weakly closed. But every strongly open set is a countable union of strongly closed spheres, again using the Lindelöf Theorem, hence $\mathcal{U} \subseteq \mathcal{W} \supseteq \mathcal{U} = \mathcal{W}$.

To show that every strongly closed sphere is weakly closed, it suffices to show that the unit ball $B_1$ is weakly closed, or equivalently $B_1^c = \{x : |x| > 1\}$ is weakly open. Suppose $|y| > 1$. By the
Hahn-Banach Theorem there exists \( f \in X' \) such that \( f(y) = |y| \) and \( |f| = 1 \), so that \( |f(x)| \leq |x| \). Then \( W = \{ x : |f(x) - |y|| < |y| - 1 \} \) is a weakly open nhd. of \( y \) and \( W \subseteq B_1^c \).

It should be noted that the Hahn-Banach Theorem can also be used to show that the weak topology \( \mathcal{W} \) is Hausdorff. In the case of the conjugate space \( X' \), it follows from the definition that \( (X', \mathcal{W}') \) is Hausdorff.

A topological space \((X, \mathcal{U})\) is said to be **sequentially compact** \((K_1)\) iff every sequence in \( X \) has a convergent subsequence, and **compact** \((K_2)\) iff every open cover of \( X \) has a finite subcover.

If \( X \) is \( C_1 \) and \( K_2 \), then \( X \) is \( K_1 \) \((C_1K_2 \subseteq K_1)\). For suppose \( X \) is \( C_1 \) but not \( K_1 \), and let \( x_n \) be a sequence in \( X \) with no convergent subsequence. For each \( x \in X \), choose a nhd. \( V_x \) such that \( x_n \) is eventually in \( V_x^c \); this is possible since \( X \) is \( C_1 \) and \( x_n \) has no convergent subsequence. Then \( \zeta = \{ V_x : x \in X \} \) is an open cover of \( X \) which has no finite subcover, because \( x_n \) is eventually outside the union of any finite subclass of \( \zeta \) by the way the sets \( V_x \) were chosen.

If \( X \) is \( C_2 \) and \( K_1 \), then \( X \) is \( K_2 \) \((C_2K_1 \subseteq K_2)\). For suppose \( X \) is \( C_2 \) but not \( K_2 \), and let \( \zeta \) be an open cover with no finite subcover. By the Lindelöf Theorem there is a countable subcover, say \([U_n]\). Choose \( x_n \) inductively so that \( x_n \in \bigcap_{k=1}^{n} U_k^c \); this is possible since \([U_n]\) has no finite subcover. Then \( x_n \) clearly has no convergent subsequence; because if \( x \in U_m \), then \( x_n \in U_m^c \) for all \( n \geq m \), so that no subsequence can converge to \( x \).

A subset \( A \subseteq X \) is said to be compact or sequentially compact iff
it is a compact or sequentially compact subspace, respectively, in its relative topology. It is easy to see that a closed subset of a compact set is compact, with either notion of compactness.

Conversely a \( K_1 \) subset of a \( C_1 T_2 \) space is closed, and a \( K_2 \) subset of a \( T_2 \) space is closed. Suppose \( X \) is \( C_1 T_2 \), and let \( \emptyset \subset X \) be \( K_1 \). If \( x \in S \), then there is a sequence \( x_n \in S \) such that \( x_n \to x \); and there is a subsequence \( x'_n \) such that \( x'_n \to x' \in S \) since \( S \) is \( K_1 \). But also \( x'_n \to x \), hence \( x = x' \in S \) since \( X \) is \( T_2 \), which implies \( S \) is closed. Now suppose \( X \) is \( T_2 \), and let \( A \subset X \) be \( K_2 \) and \( y \in A^c \). For each \( x \in A \) there exist open sets \( U_x \in \tau_x \) and \( V_x \in \tau_y \) such that \( U_x \cap V_x = \emptyset \); and \( \{U_x : x \in A\} \) is an open cover of \( A \), hence has a finite subcover \( \{U_{x_k} : k = 1, \ldots, n\} \). The sets \( U = \bigcup_{k=1}^{n} U_{x_k} \in \tau_x \) and \( V = \bigcap_{k=1}^{n} V_{x_k} \in \tau_y \) are disjoint, thus \( A \) is closed.

A top. space \( X \) is locally compact (\( lK \)) iff each point has a closed compact nhd. Every locally compact Hausdorff space is regular. (See KELLEY, p. 141, Theorem 9 and p. 146, Theorem 17.)

Let \( X \) be a \( p \)-metric \( (M_0) \) space, \( \varepsilon > 0 \), and \( S \subset X \). Then a set \( E \subset X \) is called an \( \varepsilon \)-net for \( S \) iff, for every \( x \in S \), there exists a point \( x_\varepsilon \in E \) such that \( d(x, x_\varepsilon) < \varepsilon \). The set \( S \) is totally bounded iff, for every \( \varepsilon > 0 \), there exists a finite \( \varepsilon \)-net for \( S \).

Every totally bounded \( p \)-metric space \( X \) is \( C_2 \). To show this, for each \( n = 1, 2, \ldots \) choose a finite \( \frac{1}{n} \)-net for \( X \), say \( [x_{n1}, \ldots, x_{nk_n}] = E_n \); so that for each \( x \in X \) there exists \( x_{nj} \in E_n \) such that \( x \in S(x_{nj}, \frac{1}{n}) \). Then \( J = [S(x_{nj}, \frac{1}{n}) : j = 1, \ldots, k_n; n=1,2,\ldots] \) is a countable base; because for each \( x \in X \) and \( \varepsilon > 0 \), there is some
n such that \( S(x, \frac{1}{n}) \subset S(x, \frac{\varepsilon}{2}) \), and then \( x \in S(x_n, \frac{1}{n}) \subset S(x, \varepsilon) \) for some \( x_n \in E_n \).

A set \( S \) is **conditionally compact** iff every sequence in \( S \) has a convergent subsequence. Note that a set \( S \) is \( K_1 \) if it is closed and conditionally compact, and that \( S \) is totally bounded if and only if \( \overline{S} \) is totally bounded.

**Hausdorff Compactness Theorem**

If \( X \) is a complete \( p \)-metric space, then a set \( S \subset X \) is conditionally compact iff it is totally bounded. A \( p \)-metric space is compact iff it is totally bounded and complete.

**Proof.** Suppose \( S \) is not totally bounded. Then for some \( \varepsilon > 0 \), there is no finite \( \varepsilon \)-net for \( S \). Choose any point \( x_1 \in S \). Since \([x_1] \) is not an \( \varepsilon \)-net, \( x_2 \in S \) can be chosen so that \( d(x_1, x_2) > \varepsilon \); since \([x_1, x_2] \) is not an \( \varepsilon \)-net, \( x_3 \in S \) can be chosen so that \( d(x_1, x_3) \neq d(x_2, x_3) > \varepsilon \). By the principle of inductive definition a sequence \([x_n] \subset S \) exists such that \( d(x_m, x_n) > \varepsilon \) for \( m \neq n \), which implies that \( S \) is not conditionally compact. (Note that the necessity holds whether \( X \) is complete or not.)

Now suppose \( S \) is totally bounded, and let \([x_n] \) be any sequence in \( S \). For each \( k = 1, 2, \ldots \) let \([a_{jk} : j = 1, \ldots, p_k] \) be a \( \frac{1}{k} \)-net for \( S \). Then for each \( k = 1, 2, \ldots \)

\[
S \subset \bigcup_{j=1}^{n_k} S(a_{jk}, \frac{1}{k})
\]

by definition of an \( \varepsilon \)-net. Note that it suffices to assume that \([x_n] \) has an infinite number of distinct points. Thus, for \( k = 1 \), at least
one of the spheres \( S(a_j, 1) \) say \( S_1 \), contains an infinite subsequence \( x_{1,n} \) for \( k = 2 \) some \( S_2 = S(a_j, \frac{1}{2}) \) contains a subsequence \( x_{2,n} \) of \( x_{1,n} \) and so on. By the usual Cantor diagonal process, the diagonal sequence \( x_{n,n} \) is a subsequence of \( x_{k,n} \) for \( k = 1, 2, \ldots \).

This implies that

\[
x_{n,n} \in S_n = S(a_j, \frac{1}{k}) \quad \text{for} \quad n \geq k,
\]

hence \( d(x_{n,n}, x_{k,k}) \leq d(x_{n,n}, a_j) + d(a_j, x_{k,k}) < \frac{2}{k} \). Therefore \( x_{n,n} \) is a Cauchy sequence and, since \( X \) is complete, \( x_{n,n} \) converges to at least one point in \( X \), which implies that \( S \) is conditionally compact.

Evidently \( K_1 \) and \( K_2 \) compactness are equivalent for \( p \)-metric spaces, since every \( p \)-metric space is \( C_1 \) and every \( K_1 \) metric space is totally bounded, hence \( C_2 \). To prove the second assertion, it suffices to show that every compact \( p \)-metric space is complete. But if \( X \) is compact and \( x_n \) is a Cauchy sequence, then there is a convergent subsequence \( x_{n_k} \to x \); and \( d(x_n, x) \leq d(x, x_{n_k}) + d(x_{n_k}, x) \implies x_n \to x \). \( \blacksquare \)
CHAPTER VI

REGULAR MEASURES AND THE CONSISTENCY THEOREM

So far, the existence of the basic pr. space \((\Omega, \mathcal{A}, P)\) has been postulated, and the pr. distribution of a r.v. \(X\) in a measurable space \((X, \mathcal{B})\) has been defined by \(P_x B = P[X \in B]\). However, in pr. theory the domain space \((\Omega, \mathcal{A}, P)\) of a r.v. \(X\) is immaterial, except insofar as it provides a common frame of reference for all r.v.'s under consideration, and r.v.'s are used only as transformations from one pr. space to another, which preserve pr. distributions. Thus the only important thing about a r.v. \(X\) is its pr. distribution \(P_X\). In fact, in practice the basic pr. space \((\Omega, \mathcal{A}, P)\) is unknown, hence even the r.v. \(X\) is unknown. This is because an actual physical experiment produces nothing but a pr. distribution \(Q\) on \(\mathcal{B}\), or more generally a family \([Q_t : t \in T]\) of pr. distributions. If a single pr. distribution \(Q\) is involved, then there always exists a pr. space \((\Omega, \mathcal{A}, P)\) and a r.v. \(X : \Omega \rightarrow X\) such that \(P_X = Q\); namely \((\Omega, \mathcal{A}, P) = (X, \mathcal{B}, Q)\) and \(X(x) = x\).

Consider a sequence \(X = [X_n : n = 1, 2, \ldots]\) of r.v.'s in a measurable space \((X', \mathcal{B}')\), and write \(X^n = [X_k : k = 1, \ldots, n]\) and \((X^n, \mathcal{B}^n) = \prod_{k=1}^{n}(X_k, \mathcal{B}_k)\) for \(n = 1, 2, \ldots, \infty\), where \(X_k = X'\) and \(\mathcal{B}_k = \mathcal{B}'\). Define the projections \(p_{nm} : X^n \rightarrow X_m\), \(q_{nm} : X^n \rightarrow X^m\) \((m \leq n)\) by \(p_{nm}(x^n) = x_m\), \(q_{nm}(x^n) = x^m\), and for \(A^m \subset X^m\) write \(A^m \times X^{n-m} = q_{nm}^{-1} A^m\); subscripts and superscripts \(n = \infty\) will be dropped.
It follows easily that \( q_{nm} q_n = q_m \), so that

\[
A^m \times A^{-m} = q_m^{-1} A_m = q_n^{-1} q_{nm} A_m = A^m \times X^{n-m} \times X^{-n}.
\]

The sequence \( X \) can be regarded as a r.v. in the product space \( \mathcal{X} \), and its pr. distribution \( P_0 = P_X \) on \( \mathcal{B} \), defined by \( P_0 B = P[X \in B] \), determines the joint pr. distributions \( P_n = P_X^n \) on \( \mathcal{B}^n \):

\[
P^n B^n = P[X^n \in B^n] = P[X \in B^n \times X^{-n}] = P_0 B^n \times X^{-n}.
\]

The pr. distributions \( P_n \) are consistent:

\[
m < n, B^m \in \mathcal{B}^m \implies P^m B^m = P^n B^m \times X^{n-m} = P_{nm} B^m.
\]

Conversely, suppose consistent pr. distributions \( P^n \) on \( \mathcal{B}^n \) are given. The problem is to construct a pr. space \((\Omega, \mathcal{A}, P)\) and a sequence \( X = [X_n : n = 1, 2, \ldots] \) of r.v.'s \( X_n : \Omega \to \mathcal{X} \) such that \( P_X^n = P^n \).

It suffices to construct a pr. \( Q \) on \( \mathcal{B} \) such that

\[
Q^n B^n \equiv Q B^n \times X^{-n} = P^n B^n (B^n \in \mathcal{B}^n);
\]

then take

\[
(\Omega, \mathcal{A}, P) = (\mathcal{X}, \mathcal{B}, Q) \quad \text{and} \quad X_n(x) = x_n.
\]

The classical Kolmogorov Consistency Theorem says this is always possible if \( \mathcal{X} \) is the real line and \( \mathcal{B} \) is the Borel \( \sigma \)-field. But such a pr. \( Q \) does not always exist; for a counterexample see HALMOS [1], p. 214, prob. 3.

In this chapter, a generalization of the Kolmogorov Consistency Theorem will be proved. The proof leans heavily on some of the
topological concepts considered in the previous chapter, especially the concept of compactness. The proof also depends on the Caratheodory Extension Theorem and the concept of regular measures, which will be examined first.

So far in this paper, measures have been assumed to be given. But sometimes it is desirable to construct a measure \( \mu \) on a \( \sigma \)-field \( \mathcal{C} \) such that \( \mu = \mu \) on \( \mathcal{C} \), where \( \mu \) is a given measure on \( \mathcal{C} \). If \( \mathcal{C} \) is a ring such that \( X \) is a countable union of \( \mathcal{C} \) sets, then the existence of such measures \( \bar{\mu} \) is guaranteed by the following famous theorem due to Caratheodory.

**Caratheodory Extension Theorem.**

If \( \mu \) is a \( \sigma \)-finite measure on a ring \( \mathcal{C} \), then there exists a unique measure \( \mu \) on \( \mathcal{C} \) such that \( \mu = \mu \) on \( \mathcal{C} \); \( \mu \) is also \( \sigma \)-finite.

**Proof.** The existence proof is based on the concept of an outer measure. A set function \( m^0 \) on a class \( \mathcal{G} \) of subsets of \( X \) is an outer measure iff

1. \( \sum_{n=1}^{\infty} \mathcal{G} \subseteq \mathcal{G} \quad m^0 \left( \bigcup_{n=1}^{\infty} \mathcal{G} \right) = \sum_{n=1}^{\infty} m^0 \mathcal{G} \)
2. \( A, B \in \mathcal{G} ; A \subseteq B \Rightarrow m^0 A \leq m^0 B \)
3. \( m^0 \emptyset = 0 \)

If \( m^0 \) is an outer measure on \( \mathcal{G}(X) \), then a set \( A \subseteq X \) is said to be \( m^0 \)-measurable iff

\[
m^0 S = m^0 (AS) + m^0 (A^c S) \quad \text{for every} \quad S \subseteq X.
\]

**Lemma 1.** If \( m^0 \) is any outer measure on \( \mathcal{G}(X) \) and \( \mathcal{M} \) is the class of all \( m^0 \)-measurable sets, then \( \mathcal{M} \) is a \( \sigma \)-field, and the
restriction of \( m^0 \) to \( M^0 \) is a measure.

**Lemma 2.** If \( \mu \) is a measure on a ring \( \mathcal{X} \) such that \( X \) is the union of a countable number of \( \mathcal{X} \)-sets, and if

\[
\mu^0 S = \inf \left[ \sum \mu A_n : A_n \in \mathcal{X}, \bigcup A_n \supset S \right]
\]

for all \( S \subseteq X \), then \( \mu^0 \) is an outer measure on \( \mathcal{B}(X) \). For the proofs of these lemmas, see LOEVE, p. 88.

Now let \( m^0 = \mu^0 \). Clearly \( \mu^0 A = \mu A \) for \( A \in \mathcal{X} \). Furthermore \( \mathcal{X} \subseteq m^0 \). To see this, let \( A \in \mathcal{X} \), \( S \subseteq X \), and \( \epsilon > 0 \), and choose \( A_n \in \mathcal{X} \) so that \( S \subseteq \bigcup A_n \) and

\[
\mu^0 S + \epsilon \geq \sum \mu A_n = \sum \mu AA_n + \sum \mu A^c A_n \geq \mu^0 AS + \mu^0 A^c S.
\]

Since \( \epsilon \) is arbitrary, \( \mu^0 S \geq \mu^0 AS + \mu^0 A^c S \), and the opposite inequality follows by subadditivity. Thus \( \mathcal{X} \subseteq m^0 \), and it suffices to let \( \mu \) be the restriction of \( \mu^0 \) to \( \mathcal{X} \).

To prove the uniqueness, let \( \mu_1 \) and \( \mu_2 \) be two extensions of \( \mu \) to \( \mathcal{X} \) such that \( \mu_1 = \mu_2 = \mu \) on \( \mathcal{X} \), choose \( C_n \in \mathcal{X} \) so that \( C_n \uparrow X \) and \( \mu_1 C_n = \mu_2 C_n = \mu C_n < \infty \) for each \( n \), and consider

\[
\mathcal{M} = \{ A \in \mathcal{X} : \mu_1 A C_n = \mu_2 A C_n \text{ for all } n \}.
\]

Let \( A_k \in \mathcal{M} \) be a monotone sequence, and \( A = \lim A_k \). Then for each fixed \( n \),

\[
\mu_1 A C_n = \lim_{k} \mu_1 A_k C_n = \lim_{k} \mu_2 A_k C_n = \mu_2 A C_n,
\]

by the Continuity Theorem, so \( \mathcal{M} \) is a monotone class. Therefore \( \mathcal{X} \supseteq \mathcal{M} \supseteq \mathcal{X} \supseteq \mathcal{X} \subseteq \mathcal{M} \) by the Monotone Class Theorem, which means
Now for any \( A \in \mathcal{C} \), \( AC_n \uparrow A \), therefore

\[
\mu_1 A = \lim \mu_1 AC_n = \lim \mu_2 AC_n = \mu_2 A
\]

by the Continuity Theorem, which completes the proof.

Suppose \( \mu \) is a content on a class \( \mathcal{C} \) in a T.M. space \((X, \mathcal{U}, \mathcal{B})\), and let \( \mathcal{K} \) be the class of all closed compact subsets of \( X \). Then a set \( B \in \mathcal{C} \) is said to be

1. **outer regular** iff \( \mu B = \inf_{A \in \mathcal{C}, B \subset A} \mu A \)

2. **inner regular** iff \( \sup_{C \in \mathcal{K}, B \supseteq C} \mu C \)

3. **regular** iff both (1) and (2) hold.

The content \( \mu \) is called a **regular content** iff every set \( B \in \mathcal{C} \) is regular with respect to \( \mu \).

A **semifield** is a nonempty class \( \mathcal{D} \) of subsets of \( X \) such that,

1. if \( D, D' \in \mathcal{D} \), then
   - \( DD' \in \mathcal{D} \)
   - \( D^c \) can be written as a finite sum of \( \mathcal{D} \)-sets, say \( D^c = \sum_{j=1}^n E_j \), such that \( D_k = D + \sum_{j=1}^k E_j \in \mathcal{D} \) for each partial sum \( k = 1, \ldots, n \).

   It follows that \( X \in \mathcal{D} \), \( \emptyset \in \mathcal{D} \), and

2. every proper difference \( D' - D \) of two \( \mathcal{D} \)-sets \((D \subset D')\) can be written as a finite sum of \( \mathcal{D} \)-sets, say \( D' - D = \sum_{j=1}^n E_j \), such that \( D_k = D + \sum_{j=1}^k E_j \in \mathcal{D} \) for each partial sum \( k = 1, \ldots, n \).

A **semiring** is a nonempty class \( \mathcal{D} \) satisfying (1) and (2)', and it follows from (2)' that every semiring contains \( \emptyset \), taking \( D = D' \).
Clearly a semifield is a semiring containing $X$.

**Semiring Lemma**

1. Every additive set function $\mu$ on a semiring $\mathcal{D}$ is finitely additive.

2. If $\mu$ is a measure (content) on a semiring $\mathcal{D}$, then there exists a unique measure (content) $\mu'$ on the class $\mathcal{D}^*$ of all finite sums of $\mathcal{D}$-sets such that $\mu' = \mu$ on $\mathcal{D}$.

3. A finite, regular content on a semiring $\mathcal{D}$ in a T.M. space is a measure on $\mathcal{D}$.

**Proof.**

1. It must be shown that if $D = \sum_{1}^{m} D_i$, where $D_i \in \mathcal{D}$, then $\mu D = \sum_{1}^{m} \mu D_i$. This is true by hypothesis for $m = 2$; suppose it is true with $m$ replaced by $m - 1$ ($m \geq 3$), and write $D = D_1 + \sum_{1}^{n} E_j$, where $E_j \in \mathcal{D}$ and $D_1 + \sum_{1}^{k} E_j \in \mathcal{D}$ for $k = 1, \ldots, n$. It follows by a separate induction that $\mu D = \mu D_1 + \sum_{1}^{n} \mu E_j$. Furthermore

$$D_i = \sum_{j=1}^{n} D_i E_j \quad (i = 2, \ldots, m),$$

where $D_i E_j \in \mathcal{D}$ and $\sum_{j=1}^{k} D_i E_j \in \mathcal{D}$ for each partial sum $(k = 1, \ldots, n)$, hence also $\mu D_i = \sum_{j=1}^{n} \mu D_i E_j$; and $E_j = \sum_{i=2}^{m} D_i E_j \quad (j = 1, \ldots, n)$ implies

$$\mu E_j = \sum_{i=2}^{m} \mu D_i E_j \quad \text{by the induction hypothesis. Therefore}$$
\[ \mu D = \mu D_1 + \sum_{j=1}^{n} \sum_{i=2}^{m} \mu D_1 E_j = \mu D_1 + \sum_{i=2}^{n} \sum_{j=1}^{m} \mu D_1 E_j = \mu D_1 + \sum_{i=2}^{m} \mu D_i. \]

(2) Suppose \( \mu \) is a measure (content) on \( \mathcal{D} \), and for

\[ D = \sum_{j=1}^{m} D_j = \sum_{k=1}^{n} E_k \in \mathcal{D}^r \quad (D_j, E_k \in \mathcal{D}) \]

define

\[ \mu' D = \sum_{j=1}^{m} \mu D_j = \sum_{k=1}^{n} \sum_{i=1}^{m} \mu D_j E_k = \sum_{k=1}^{n} \mu E_k. \]

Note that \( \mu' \) is well defined and uniquely determined, and \( \mu' = \mu \) on \( \mathcal{D} \).

Let \( D = \sum_{i=1}^{m} E_i \),

\[ D_j = \sum_{k=1}^{n} E_{jk} \quad (E_i, E_{kj} \in \mathcal{D}) . \]

Then

\[ \mu' D = \sum_{i=1}^{m} \mu E_i = \sum_{i=1}^{m} \sum_{j=1}^{n} \sum_{k=1}^{n} \mu E_i E_{jk} = \sum_{j=1}^{m} \sum_{k=1}^{n} \sum_{i=1}^{m} \mu E_i E_{jk} = \sum_{j=1}^{m} \mu' D_j. \]

(3) Let \( D = \sum_{i=1}^{n} D_n \), where \( D, D_n \in \mathcal{D} \). It was shown above that \( \mu \) determines its extension to a content \( \mu' \) on \( \mathcal{D}^r \); for convenience in notation, write \( \mu' = \mu \).

For each \( n \), \( \mu \sum_{i=1}^{n} D_j = \sum_{i=1}^{n} \mu D_j \leq \mu D \), hence \( \sum \mu D_n \leq \mu D \).

Now let \( \varepsilon > 0 \) be given.

Since \( \mu \) is inner regular, there is a set \( C \in \mathcal{D} \) such that

\[ D \supseteq C \varepsilon \mathcal{K} \text{ and } \mu C > \mu D - \varepsilon. \]
Since $\mu$ is outer regular, for each $n$ there is a set $E_n \in \mathcal{D}$ such that $D_n \subseteq E_n^\circ$ and

$$\mu E_n < \mu D_n + \frac{\varepsilon}{2^n}.$$ 

Now $[E_n^\circ]$ is an open cover of $C^-$, hence there is a finite subcover, say $[E_k^\circ : k = 1, \ldots, n]$. It follows that $C \subseteq \bigcup_{k=1}^n E_k$, whence

$$\mu D - \varepsilon < \mu C \leq \sum_{k=1}^n \mu E_k < \sum \mu D_n + \varepsilon,$$

which implies that $\mu D \leq \sum \mu D_n$ and $\mu$ is a measure.

It should be noted that the Extension Theorem is true for semirings instead of rings, using the Semiring Lemma (2).

If $\xi$ is any class of subsets of $X$ which contains $X$ and $\emptyset$ and is closed under finite unions and intersections, and $\mathcal{D}$ is the class of all proper differences of $\xi$-sets, then $\mathcal{D}$ is a semifield. For if $D = E - F$, $D' = E' - F' \in \mathcal{D}$, then $DD' = EE' - EE' (F \cup F') \in \mathcal{D}$; and $D^C = (E F^C)^C = F + E^C$ where $F$ and $E^C \in \mathcal{D}$ and $D + F = E \in \mathcal{D}$. If $\xi$ does not contain $X$, then $\mathcal{D}$ is still a semiring. For if $D \subseteq D'$, with the above notation, then $D' - D = [F - FF'] + [E' - (E \cup F')]$, and $D + [F - FF'] = E - FF' \in \mathcal{D}$.

If $\mathcal{D}$ is a semifield and $\zeta$ is the class of all finite sums of $\mathcal{D}$-sets, then $\zeta$ is a field. For if $A = \sum_{j=1}^m D_j \in \zeta$, $B = \sum_{k=1}^n E_k \in \zeta$, then clearly $AB = \sum_{j=1}^m \sum_{k=1}^n D_j E_k \in \zeta$; hence also $A^C = \sum_{j=1}^m D_j^C \in \zeta$, since each $D_j^C \in \zeta$ by axiom (2) and $\zeta$ is closed under pairwise (hence finite) intersection. If $\mathcal{D}$ is only a semiring, then $\zeta$ is still a ring.
Thus if $\mathcal{X}$ is any class containing $\emptyset, X$ which is closed under finite unions and intersections, and if $\mathcal{D}$ and $\mathcal{Z}$ are the classes defined above, then $\mathcal{D}$ is a semifield and $\mathcal{Z}$ is a field; furthermore

$$\mathcal{Z} = \mathcal{D} = \mathcal{X}.$$  

(If $X \notin \mathcal{X}$, then a similar statement holds for semirings, rings, and minimal rings.) In particular, if $(X, \mathcal{U})$ is a top. space, $\mathcal{D}$ is the class of all proper differences of closed sets, and $\mathcal{Z}$ is the class of all finite sums of $\mathcal{D}$-sets, then

$$\mathcal{U}^{c} = \mathcal{Z} \supset \overline{\mathcal{U}} = \overline{\mathcal{U}^{c}} = \overline{X} = \overline{\mathcal{X}}.$$  

These relations will be useful in the proof of the Regular Measures Theorem. Recall that the same type of construction was used in Chapter IV, in the proof of the Independence Theorem.

A set $A$ in a top. space $X$ will be called a $G_{6}$ iff there exists a decreasing sequence $U_{n}$ of open sets such that $A = \bigcap_{n} U_{n}$, and $X$ will be called a $G_{6}$-space iff every closed subset of $X$ is a $G_{6}$. Every $p$-metric space is a $G_{6}$-space: if $A$ is closed and $U_{n} = \{x : d(x, A) = \inf d(x, y) < \frac{1}{n}\}$, then $A = \bigcap_{n} U_{n}$. Every regular $L_{2}$ space is a $G_{6}$-space.

A set $A$ in a T.M. space $(X, \mathcal{U}, \mathcal{B})$ will be called a $\mathcal{B}G_{6}$ iff $A \in \mathcal{B}$ and there is a sequence of open sets $U_{n} \in \mathcal{B}$ such that $U_{n} \downarrow A$.

A top. space $X$ will be called $\sigma$-compact ($\sigma K$) iff there exists an increasing sequence of closed compact sets $C_{n}$ such that $X = \bigcup_{n} C_{n}$. For example, if $X$ is any Banach space, then $X'$ is $\sigma K$ with respect to the $\mathcal{W}'$ topology, since all strongly closed spheres are $\mathcal{W}'$ closed.
and \( \mathcal{W} \) compact. It follows easily that every \( \sigma \mathcal{K} \) space is \( L_1 \), and every \( \mathcal{K} \), \( L_1 \) space is \( \sigma \mathcal{K} \). Furthermore, the product of a finite number of \( \sigma \mathcal{K} \) top. spaces is \( \sigma \mathcal{K} \).

A T.M. space \( (X, \mathcal{U}, \mathcal{B}) \) will be called \( \overline{\mathcal{M}}_{02} \) or \( \sigma \mathcal{K}_{02} \) iff \((X, \mathcal{U})\) is the same, respectively, and \( \mathcal{B} = \overline{\mathcal{U}} \); and will be called \( \Pi[\sigma \mathcal{K}_{02}] \) iff it is the product of a finite number of \( \sigma \mathcal{K}_{02} \) T.M. spaces.

Suppose \((X, \mathcal{U}, \mathcal{B})\) is a T.M. space, \( \mathcal{K} \) is the class of all closed compact subsets of \( X \), and \( \mu \) is a measure on \( \mathcal{B} \). Then \( X \) is said to be \( \mu \)-a.s. \( \sigma \)-compact iff there exists a sequence \( \{C_n\} \) such that \( C_n \uparrow C \) and \( \mu C^C = 0 \). (In the terminology of HALMOS [1], p. 74, this means there exists an increasing sequence of closed compact measurable sets whose union is a thick set with respect to \( \mu \).) A T.M. space will be called \( \text{a.s. } \sigma \)-compact (a.s. \( \sigma \mathcal{K} \)) iff it is \( \mu \)-a.s. \( \sigma \)-compact with respect to every finite measure \( \mu \) on \( \mathcal{B} \).

The following theorem is a problem in HALMOS [1], p. 40 (for metric spaces).

**Theorem.** Let \( X \) be a separable, complete p-metric space (\( \overline{\mathcal{M}}_{02} \) space) with metric topology \( \mathcal{U} \), and let \( \mu \) be a finite measure on \( \mathcal{B} = \overline{\mathcal{U}} \).

Then there exists a sequence of closed compact sets \( \{C_n\} \) such that \( C_n \uparrow C \) and \( \mu C = \mu X \). Therefore every \( \overline{\mathcal{M}}_{02} \) space is a.s. \( \sigma \mathcal{K} \).

**Proof.** It suffices to assume that \( \mu X = 1 \).

Let \( \{x_n\} \) be a countable dense set, and \( 0 < \varepsilon < 1 \). For each \( k, m = 1,2, \ldots \), define

\[
F_{km} = \bigcup_{n=1}^{m} \overline{S}(x_n, \frac{1}{k})
\]
Let $m_1$ be the smallest positive integer such that $\mu F_{1m_1} > 1 - \varepsilon$.

Clearly $m_1$ exists, because $F_{1m} \uparrow \mathbb{X}$ since $[x_n]$ is dense, which implies that $\mu F_{1m} \uparrow \mu \mathbb{X} = 1$ by the Continuity Theorem. Similarly, $F_{1m_1} F_{2m} \uparrow F_{1m_1}$ ($m \to \infty$), hence

$$\mu F_{1m_1} F_{2m} \uparrow \mu F_{1m_1} > 1 - \varepsilon.$$ 

Let $m_2$ be the smallest positive integer such that

$$\mu F_{1m_1} F_{2m_2} > 1 - \varepsilon.$$ 

Proceeding by induction, let $m_k$ be the smallest positive integer such that

$$\mu \bigcap_{j=1}^{k} F_{jm_j} > 1 - \varepsilon \quad (k = 1, 2, \ldots).$$

Let $D_k = \bigcap_{j=1}^{k} F_{jm_j}$, and $D = \bigcap D_k = \bigcap F_{km_k} = \bigcup_{n=1}^{m_k} \overline{s}(x_n, \frac{1}{k})$, so that $\mu D = \lim \mu D_k \geq 1 - \varepsilon$ by the Continuity Theorem. Furthermore, $D$ is closed; and $D$ is compact by the Hausdorff Theorem since $[x_n]_{m_k}$ is a $\frac{1}{k}$-net for $D$ for $k = 1, 2, \ldots$. For if $x \in D$, then for each $k, x \in \overline{s}(x_n, \frac{1}{k})$ for some $n = 1, \ldots, m_k$.

Now choose for each $n$ a closed compact set $D_n$ such that $\mu D_n \geq 1 - \frac{1}{n}$, and let $C_n = \bigcup_{k=1}^{n} D_k$ and $C = \bigcup C_n$. Then each $C_n$ is closed and compact, and $\mu C_n \geq \mu D_n \geq 1 - \frac{1}{n}$, hence $\mu C = \lim \mu C_n = 1$ by the Continuity Theorem.

Suppose $(X, \mathcal{U}, \mathcal{B})$ is a T.M. space, $\mathcal{K}$ is the class of all closed compact subsets of $X$, and $\mu$ is a measure on $\mathcal{B}$. A set $B \in \mathcal{B}$ is
(1) **outer regular** iff \( \mu_B = \inf_{B \subseteq A} \mu_A \)

(2) **inner regular** iff \( \mu_B = \sup_{B \supseteq C} \mu_C \)

(3) **regular** iff both (1) and (2) hold.

A class \( \xi \subseteq \mathcal{B} \) is regular iff every set \( B \in \xi \) is regular, and the measure \( \mu \) is regular iff \( \mathcal{B} \) is regular.

It will be shown that if \( X \) is either \( \mathbb{R}^n \) or \( \Pi_{\sigma KG_\delta} \), then every finite measure \( \mu \) on \( \mathcal{B} \) is regular. The proof is based on the methods of HALMOS [1], p. 224-228, who deals with locally compact Hausdorff spaces.

**Lemma 1.**

(a) The union of any sequence of outer regular sets is outer regular, and the union of an increasing sequence of inner regular sets is inner regular.

(b) If \( \mu \) is finite, then the intersection of any sequence of inner regular sets is inner regular, and the intersection of a decreasing sequence of outer regular sets is outer regular.

**Proof.** (a) Let \( [B_n] \) be any sequence of outer regular sets, \( B = \bigcup B_n \), and \( \varepsilon > 0 \). If \( \mu_B = \infty \), then \( B \) is trivially outer regular. Assume \( \mu_B < \infty \), and for each \( n \) choose an open measurable set \( V_n \supseteq B_n \) such that \( \mu V_n < \mu B_n + \frac{\varepsilon}{2^n} \). Let \( V = \bigcup V_n \supseteq B \). Then

\[
V - B = \bigcup_m [V_m \cap B_m^c] \subseteq \bigcup_m V_m B_m = \bigcup_m V_m - B_m,
\]

therefore \( \mu V - \mu B \leq \sum \mu V_m - \mu B_m \leq \sum \frac{\varepsilon}{2^m} = \varepsilon \supseteq B \) is outer regular.

Now suppose \( [B_n] \) is an increasing sequence of inner regular sets,
and let $B = \bigcup_{n} B_n$. Then $\mu_{B_n} \uparrow \mu_B$ by the Continuity Theorem. Let $r < \mu_B$, choose $m$ so that $r < \mu_{B_m} \leq \mu_B$, then choose a closed compact measurable set $C$ so that $C \subseteq B_n \subseteq B$ and $\mu_C > r$. Thus $B$ is inner regular. The proof of (b) is similar (see HALMOS [1], p. 226).

Lemma 2. Every finite sum of regular sets is regular. If $\mu$ is finite and $\zeta$ is any class of closed (open) regular sets, then every proper difference of two $\zeta$ sets is regular.

Proof. It follows from lemma 1 that every finite sum of outer regular sets is outer regular; and it follows immediately from the definition that every finite sum of inner regular sets is inner regular, since a finite union of closed compact measurable sets also has these properties.

The second assertion will be proved for closed sets; the proof for open sets is similar. Let $A, B \in \zeta$, $A \supseteq B$, and $\varepsilon > 0$. Since $A$ is inner regular, there is a closed compact measurable set $C \subseteq A$ such that $\mu_C > \mu_A - \varepsilon$; and since $B$ is outer regular, there is an open measurable set $V \supseteq B$ such that $\mu_V < \mu_B + \varepsilon$. Then $C - V \subseteq A - B$, $C - V$ is a closed compact measurable set, and

$$\mu(C - V) = \mu_C - \mu_{CV} > \mu_A - \varepsilon - \mu_B - \varepsilon = \mu(A - B) - 2\varepsilon;$$

therefore $A - B$ is inner regular. Since $A$ is outer regular, there is an open set $U$ such that $\mu U < \mu A + \varepsilon$. Thus $U - B$ is open, $A - B \subseteq U - B$, and $\mu(U - B) < \mu(A - B) + \varepsilon$, which means $A - B$ is outer regular.
Regular Measures Theorem

Let \((X, \mathcal{B}, \mathcal{G})\) be an a.s. \(\sigma\)-\(T.M.\) space; and suppose \(\mathcal{G}\) is a class of closed \(\mathcal{B}_0\)'s such that \(\mathcal{G}\) is closed under finite intersections, \(\emptyset, X \in \mathcal{G}\), and \(\mathcal{B} = \mathcal{G}\). Then every finite measure \(\mu\) on \(\mathcal{B}\) is regular.

In particular, if \(X\) is either \(\bar{M}_{02}\) or \(\Pi[\sigma\mathcal{K}_0]\), then every finite measure \(\mu\) on \(\mathcal{B}\) is regular.

Proof. Let \(\mu\) be a finite measure on \(\mathcal{B}\), and choose \(C_n \in \mathcal{B}_0\) so that \(C_n \uparrow C\) and \(\mu C = \mu X\). If \(B \in \mathcal{B}\) is closed, then \(BC_n \in \mathcal{B}_0\) for each \(n\), and \(BC_n \uparrow BC\). Thus \(\mu BC_n \uparrow \mu B\) by the Continuity Theorem; thus every closed measurable set is inner regular. Since \(\mu\) is finite, it follows by the Continuity Theorem that every \(\mathcal{B}_0\) is outer regular.

If \(\mathcal{G}^*\) is the class of all finite unions of \(\mathcal{G}\) sets, then \(\mathcal{G}^*\) is regular by the above remarks and lemma 1 (a). Furthermore, \(\mathcal{G}^*\) is closed under finite unions and finite intersections, so that the class \(\mathcal{D}\) of all proper differences of \(\mathcal{G}^*\) sets is a semifield; and \(\mathcal{D}\) is regular by lemma 2.

The class \(\mathcal{F}\) of all finite sums of \(\mathcal{D}\) sets is a field (in fact \(\mathcal{F} = \mathcal{G}\)), and \(\mathcal{F}\) is regular by lemma 2. But the class \(\mathcal{R}\) of all regular sets is a monotone class by lemma 1, hence \(\mathcal{F} \subseteq \mathcal{R}\) implies

\[\mathcal{B} = \mathcal{F} = \hat{\mathcal{F}} \subseteq \mathcal{R}\]

by the Monotone Class Theorem.

To prove the particular assertion in case \(X\) is \(\bar{M}_{02}\), simply take \(\mathcal{G} = U^c\), so that \(\mathcal{G} = U = \mathcal{B}\); and recall that every \(\bar{M}_{02}\) space
is a.s. $\sigma K$, and every closed subset of a $M_0$ space is a $G_b$.

Suppose $(X, \mathcal{U}, \mathcal{B}) = \prod_{i=1}^{m} (X_i, \mathcal{U}_i, \mathcal{B}_i)$ is the product of a finite number of $\sigma K G_b$ spaces, where $\mathcal{B}_i = \overline{\mathcal{U}}_i$, and let

$\zeta = [\prod_{i=1}^{m} A_i : A_i \in \mathcal{U}_i^C]$. It follows easily that $\zeta$ is closed under finite intersections, $\mathcal{B} = \overline{\zeta}$, and each $\zeta$ set is a $\mathcal{B} G_b$. For each $i = 1, \ldots, m$, let $C_i \in C$ be a sequence of closed compact sets such that $C_i \uparrow X_i$. Then $C_n = \prod_{i=1}^{m} C_i \in \mathcal{B}^\infty$ and $C_n \uparrow X$, so that $X$ is $\sigma K$.

Let $(X, \mathcal{U}, \mathcal{B})$ be a sequence of T.M. spaces, and consider the product spaces $(X_n, \mathcal{U}_n, \mathcal{B}_n) = \prod_{k=1}^{n} (X_k, \mathcal{U}_k, \mathcal{B}_k)$ for $n = 1, 2, \ldots, \infty$; the notation introduced at the beginning of the chapter will be used. Let $\mathcal{K}_n, \mathcal{K}_n$ be the classes of all closed compact subsets of $X_n, X^n$ respectively.

Kolmogorov Consistency Theorem

Consistent, inner regular pr.'s $P^n$ on $\mathcal{B}^n$ determine a unique pr. $P$ on $\mathcal{B}$ such that

$$PB^n \times X^{-n} = P^n B^n (B^n \in \mathcal{B}^n),$$

provided that the top. spaces $(X_n, \mathcal{U}_n)$ are regular.

The inner regularity hypothesis is satisfied in particular whenever the T.M. spaces $(X_n, \mathcal{U}_n, \mathcal{B}_n)$ are either $\overline{M}_0$ or $\sigma K G_b$, where $\mathcal{B}_n = \overline{\mathcal{U}}_n$.

Proof. Let $\zeta$ be the class of all "Borel cylinders" of the form $B^n \times X^{-n}$, where $B^n \in \mathcal{B}^n$. It follows from the definitions that $\zeta$ is a field and $\mathcal{B} = \overline{\zeta}$. Define $P$ on $\zeta$ by $PB^n \times X^{-n} = P^n B^n, B^n \in \mathcal{B}^n$; it follows from the consistency hypothesis that $P$ is well defined and additive on $\zeta$. 
Therefore, by the Caratheodory Extension Theorem, it suffices to show that $P$ is a measure on $\mathcal{C}$. By the Continuity Theorem, it suffices to show that $P$ is continuous from above at $\emptyset$. That is, if $A_n \in \mathcal{C}$ and $A_n \downarrow A \in \mathcal{C}$, then $A = \emptyset \Rightarrow PA_n \downarrow 0$, or equivalently

$$PA_n > 2\varepsilon > 0 \Rightarrow A = \bigcap A_n \neq \emptyset.$$ 

It suffices to assume that $A_n = B^n \times X^{-n}$, $B^n \in \mathcal{B}^n$, since in any case there exists a sequence of sets $A'_n$ of this form such that $\bigcap A_n = \bigcap A'_n$.

By the inner regularity hypothesis, for each $n$ there exists a closed compact set $D^n \in \mathcal{B}^n$ such that $D^n \subset B^n$ and $P^n(B^n - D^n) < \varepsilon 2^{-n}$. Thus if $C_n = D^n \times X^{-n}$, then $P(A_n - C_n) = P^n(B^n - D^n) < \varepsilon 2^{-n}$.

Consider $E_n = \bigcap_{k=1}^{n} C_k \subset C_n \subset A_n$, and note that

$$A_n - E_n = \bigcup_{k=1}^{n} A_nC_k \subset \bigcup_{k=1}^{n} (A_k - C_k),$$

so that

$$P(A_n - E_n) \leq \sum_{k=1}^{n} P(A_k - C_k) < \sum_{k=1}^{\infty} \varepsilon 2^{-k} = \varepsilon.$$ 

Thus $2\varepsilon < PA_n = P(A_n - E_n) + PE_n < \varepsilon + PE_n \Rightarrow PE_n > \varepsilon$.

It follows that $E_n \neq \emptyset$ for each fixed $n$; let $x = (x^n, x^{-n})$ be a point in $E_n$ ($x$ depends on $n$ here), and note that $x^{-n} = (x_{n+1}, x_{n+2}, \ldots)$ can be chosen arbitrarily.

Since $x \in C_k = D_k \times X^{-k}$ for $k = 1, \ldots, n$, clearly $x_k \in D_k \equiv p_{kD}^D \subset X_k$; thus $x$ can be chosen so that $x_k \in D_k$ for all $k$, since $x_k$ is arbitrary for $k > n$. 

Now the projection mapping $p_{kk} : \mathbf{x}^k \to \mathbf{x}_k$ is continuous and $D^k$ is compact in $\mathbf{x}^k$, hence $D_k$ is compact in $\mathbf{x}_k$.

But since each $\mathbf{x}_k$ is regular, $D_k$ is also compact (see KELLEY, p. 141, Theorem 10 and p. 161, prob. B(b)), hence $D = \prod_{k=1}^{\infty} D_k$ is closed and compact, using the Tychonoff Product Theorem.

Thus $D_{E_n}$ is a decreasing sequence of nonempty, closed compact sets, which implies that $\bigcap D_{E_n} \neq \emptyset$. But $D_{E_n} \subseteq A_n$, hence $\bigcap A_n \neq \emptyset$.

It should be noted that if each $\mathbf{x}_k$ is $C_1T_2$, then compact $(K_2)$ can be replaced by $K_1$. In this case, each $D_k$ is $K_1$, hence also closed. It follows that $D = \prod_{k=1}^{\infty} D_k$ is closed, and $D$ is $K_1$ by the Cantor diagonal method. Thus $D_{E_n}$ is a decreasing sequence of nonempty, closed $K_1$ sets, and it is still true that $\bigcap D_{E_n} \neq \emptyset$.

The particular assertion follows from the Regular Measures Theorem and the fact that the product of a finite (or countable) number of $\overline{M}_{02}$ T.M. spaces is $\overline{M}_{02}$. For example, if $(\mathbf{x}_k, \mathbf{U}_k, \mathbf{B}_k)$ are $\overline{M}_{02}$ with p-metrics $d_k$ for $k = 1, \ldots, n$, then the p-metric $d^n$ on $\mathbf{x}^n$, defined by

$$d^n(x^n, y^n) = \sum_{k=1}^{n} d_k(x_k, y_k),$$

generates the product topology $\mathbf{U}^n$; furthermore $\overline{\mathbf{B}}^n = \overline{\mathbf{U}}^n$, and $\mathbf{x}^n$ is $\overline{M}_{02}$.

The Consistency Theorem has many important applications in modern probability theory. For example, Kolmogorov has used it to prove a generalization of Bochner's Theorem on characteristic functions and positive definiteness (compare LOEVE, p. 207, Theorem A and GRENAWER, p. 134,
Theorem 6.2.4) from the real line to Hilbert space, which in turn is used in the proof of a generalization of the Central Limit Theorem (compare LOEVE, p. 274, Theorem A and GRENANDER, p. 145, Theorem 6.5.1) from real r.v.'s to Hilbert r.v.'s. The Consistency Theorem can also be used to construct pr. distributions on direct sums of Hilbert spaces from given consistent pr. distributions on the finite direct sums (see GRENANDER, p. 139, Theorem 6.2.5), which has applications in the theory of Hilbert-valued stochastic processes.
