This invention relates to the synthesis of Mq₃-containing monomeric compounds, comprising a polymerizable moiety, an Mq₃-moiety, and an optional chemical spacer therebetween, wherein q in each instance, comprises an 8-hydroxyquinoline residue, M is a metal such as Mg, Zn, Al, Ga, or In, and a is 2 or 3 as the valence of the metal requires. For example, the polymerization of Znₙ₉₁ₙ⁻ or Alₙ₉₁ₙ⁻ containing monomers, in the presence or absence of a co-monomer, provided a Znₙ₉₁ₙ⁻ or Alₙ₉₁ₙ⁻ containing polymer, which retained the optical properties of Zn₉₁ₙ⁻ or Al₉₁ₙ⁻ in solution, respectively. The Mq₃-containing polymers may be used in, among other things, the fabrication of light-emitting diodes (LEDs).

STATEMENT OF GOVERNMENT LICENSE RIGHTS

This application claims priority to U.S. patent application Ser. No. 60/445,701, filed Feb. 6, 2003, and U.S. patent application Ser. No. 60/500,000 filed Sep. 4, 2003, each of which is incorporated herein by reference in its entirety.

TECHNICAL FIELD OF THE INVENTION

This invention relates to the field of electro-optical materials, including organic light-emitting diodes (OLEDs) and the emission and electron-transport layer of OLEDs.

BACKGROUND OF THE INVENTION

SUMMARY OF THE INVENTION

As disclosed herein, this invention encompasses the synthesis and utility of a polymer-supported metal-(8-hydroxyquinoline) complexes Mq, and derivatives and analogs of polymer-supported metal-(8-hydroxyquinoline) complexes Mq,, as well as methods of making and using these materials. In one aspect, for example, M is a metal selected from Mg, Zn, Al, Ga, or In; q is independently selected from 8-hydroxyquinoline or a substituted analog thereof, and n depends upon the stoichiometry required by the metal to form a complex of Mg(II), Zn(II), Al(III), Ga(III), or In(III). Thus, in one aspect, throughout this application, Mq,-containing monomers or polymers are exemplified for complexes of Alq3. Accordingly, Alq3-containing monomers or polymers are disclosed as examples of more general monomers containing Mgq3, Znq3, Alq3, Gaq3, or Inq3; or polymers containing Mgq3, Znq3, Alq3, Gaq3, Inq3, or combinations thereof.

In one aspect, by combining the fluorescent properties of Mq3, such as Alq3, with the processability of a polymer, the present invention can address the limited processability problem of Alq3, while taking advantage of its stability and its fluorescent properties. Because Alq3-functionalized monomers are incorporated into polymers and these Alq3-containing polymers can be used in OLEDs, these materials may potentially be fabricated using low-cost manufacturing techniques such as solution-processing and possibly in ink-jet printing. Further these materials may be used more generally as electro-optical materials for a variety of applications.

In one aspect, the present invention provides a synthesis of an Mq3-containing or Mq-functionalized compound, including a monomeric compound, wherein the Mq3-functionalized compound comprises a polymerizable moiety and an Mq3-moiety, and wherein q, in each instance, comprises an 8-hydroxyquinoline residue, M is selected from Mg, Zn, Al, Ga, or In, and n is 2 or 3, depending upon the valence of the metal. In this aspect, the Mq3-functionalized compound can further comprise a chemical spacer between the polymerizable moiety and the Mq3-moiety, wherein the chemical spacer comprises between 1 and about 30 carbon atoms.

In one aspect, the polymerizable moiety of the Mq3-functionalized compound, for example an Alq3-functionalized compound, can comprise a cyclic olefin, typically an olefin that is capable of undergoing ring-opening metathesis polymerization (ROMP), although other polymerization methods can also be used. In another aspect, this polymerizable moiety may comprise a strained cyclic olefin. In one aspect, for example, the ROMP of the Alq3-containing compound could be completed within about 12 hours under mild polymerization conditions. In yet another aspect, solubility and other properties of the resulting Alq3-functionalized polymer were tailored by the incorporation of a co-monomer. This method typically provided co-polymers that retained the optical properties of Alq3 in solution. While not intending to be bound by theory, this observation indicated that the polymer coil or backbone of the Alq3-functionalized polymer did not interfere with the luminescence properties of the Alq3 pendant group.

In yet another aspect, the present invention provides a method of making an Mq3-functionalized polymer, comprising: preparing a q3-functionalized monomer; polymerizing the monomer in the presence or absence of a co-monomer to form a q3-functionalized polymer; and reacting the polymer with a metal complex to form a Mq3-functionalized polymer.

In another aspect, the present invention provides an Mq3-functionalized compound comprising a polymerizable moiety and an Mq3-moiety, wherein q, in each instance, comprises an 8-hydroxyquinoline residue, M is selected from Mg, Zn, Al, Ga, or In, and n is 2 or 3, depending upon the valence of the metal. In another aspect, this invention provides an Mq3-functionalized polymer comprising the polymerization product of an Mq3-functionalized monomer.
In this aspect, the $M_{q,1}$-functionalized polymer can comprise the homopolymerization product of an $M_{q,1}$-functionalized monomer, or the copolymerization product of an $M_{q,1}$-functionalized monomer and a comonomer. Further, the $M_{q,1}$-containing monomer can be functionalized with at least one electron-donating group, at least one electron-withdrawing group, or a combination thereof.

In another aspect of this invention, the $M_{q,1}$-moiety of the monomer or the polymer can be functionalized with at least one electron-donating group, at least one electron-withdrawing group, or a combination thereof. In this aspect, for example, the $M_{q,1}$-moiety can be functionalized with at least one group independently selected from: a hydrocarbyl group, an oxygen group, a sulfur group, a nitrogen group, a silicon group, a germanium group, a tin group, a lead group, a boron group, an aluminum group, an inorganic group, an organometallic group, or a substituted analog thereof, any one of which having from 1 to about 30 carbon atoms; a halide; hydrogen; or any combination thereof. The inclusion of hydrogen in this list is intended to reflect that the quinoline moiety can optionally be partially saturated.

In another aspect, this invention can encompass a light-emitting diode comprising the polymerization product of the $M_{q,1}$-functionalized monomer.

Another aspect of this invention is a composition comprising the polymerization product of an $Alq_3$-functionalized monomer, wherein the $Alq_3$-functionalized monomer can comprise a polymerizable moiety and an $Alq_3$-moiety, and wherein $q$, in each instance, comprises an 8-hydroxyquinoline residue, which, in accordance with this invention, can include a residue of an 8-hydroxyquinoline-like compound, or a functionalized analog of an 8-hydroxyquinoline or an 8-hydroxyquinoline-like compound. In one aspect, for example, the polymerization product of an $Alq_3$-functionalized monomer is typically substantially non-crosslinked. Also in this aspect, the $Alq_3$-moiety of the $Alq_3$-functionalized monomer can be functionalized with at least one electron-donating group, at least one electron-withdrawing group, or a combination thereof.

In yet another aspect, this invention provides a composition that can comprise the polymerization product of at least one $Alq_3$-functionalized monomer and at least one comonomer, wherein the $Alq_3$-functionalized monomer comprises a polymerizable moiety and an $Alq_3$-moiety, and wherein $q$, in each instance, comprises an 8-hydroxyquinoline residue, which, in accordance with this invention, can include a residue of an 8-hydroxyquinoline-like compound.

In another aspect, the present invention provides a method of making an $Alq_3$-functionalized polymer, comprising: polymerizing an $Alq_3$-functionalized monomer in the presence or absence of at least one comonomer, wherein the $Alq_3$-functionalized monomer comprises a polymerizable moiety and an $Alq_3$-moiety; and wherein $q$, in each instance, comprises an 8-hydroxyquinoline residue.

In still another aspect, the present invention provides a method of functionalizing a polymer with an $Alq_3$ moiety, comprising:

- providing an $Alq_3$-functionalized monomer; and
- polymerizing an $Alq_3$-functionalized monomer in the presence or absence of at least one comonomer, wherein the $Alq_3$-functionalized monomer comprises a polymerizable moiety and an $Alq_3$-moiety; and wherein $q$, in each instance, comprises an 8-hydroxyquinoline residue.

These and other features, aspects, embodiments, and advantages of the present invention will become apparent after a review of the following detailed description of the disclosed features.

BRIEF DESCRIPTION OF THE FIGURES

FIG. 1 illustrates the UV/Visible absorption spectra of $Alq_3$, the $Alq_3$-containing monomer 9, and the series of 9:12 copolymers in CHCl₃ solution, as described in Table 1.

FIG. 2 illustrates the emission spectra of $Alq_3$ and the series of 9:12 copolymers in CHCl₃ solution, excited at 380 nm, as described in Table 1.

FIG. 3 provides examples of modified 8-hydroxyquinoline ligands used in the preparation of functionalized $Alq_3$-containing monomers and $Alq_3$-containing polymers.

FIG. 4 provides normalized solution emission spectra of selected modified polymers in chloroform.

FIG. 5 provides solid-state emission spectra of selected modified polymers on quartz.

FIG. 6 provides solid-state emission spectra of three different comonomer ratios of the $Alq_3$-polymer.

FIG. 7 provides solid-state emission spectra of three different comonomer ratios of the PVK-polymer.

FIG. 8 provides solid-state emission spectra of three different comonomer ratios of the PVK-polymer.

FIG. 9 provides examples of catalysts that can be used for polymerizing the functionalized monomers to the functionalized polymers, based on a ring-opening metathesis polymerization (ROMP) catalytic process.

FIG. 10 illustrates the solution fluorescence spectra (normalized intensity vs. wavelength (nm)) of all $Znq_3$-functionalized copolymers, excited at 380 nm, except for the Np copolymer which was excited at 330 nm.

FIG. 11 demonstrates that the emission (normalized intensity vs. wavelength (nm)) of the $Znq_3$-functionalized copolymers can be tuned solid-state from blue (427 nm) to the yellow (565 nm) through modifications on the second functionalized quinoline.

DETAILED DESCRIPTION OF THE INVENTION

The present invention addresses some of the current limitations in using $Alq_3$ and related $M_{q,1}$ compounds in electro-optical materials, including OLEDs, such as its limited processability, by providing a series of $M_{q,1}$-containing monomers, which comprise a polymerizable moiety and an $M_{q,1}$-moiety which can be functionalized, and by providing an $M_{q,1}$-containing polymer comprising the polymerization product of an $M_{q,1}$-functionalized monomer. Further, the $M_{q,1}$-containing polymer can comprise the homopolymerization product of an $M_{q,1}$-functionalized monomer, or the copolymerization product of an $M_{q,1}$-functionalized monomer and a comonomer, in which the comonomer and the polymerization conditions, including the ratio of comonomer to $M_{q,1}$-containing monomer, may be used to tailor the properties of the resulting polymer. This invention further encompasses a light-emitting diode comprising a $M_{q,1}$-functionalized polymer.

Thus, in one aspect, for example, the present invention provides $M_{q,1}$-containing polymers, where the $M_{q,1}$ complex is embedded within a polymer matrix. In this aspect, the $M_{q,1}$, such as $Alq_3$, is typically covalently attached to the polymer backbone, which can be accomplished by covalently attaching the $M_{q,1}$ moiety to the polymerizable monomer, prior to its polymerization. By providing a fully-functionalized
monomer that can be polymerized in a controlled fashion, this process substantially eliminates any crosslinking, and hence provides a fully-functionalized polymer without substantial crosslinking. Additionally, the polymer structure can be controlled and altered by using co-monomers to tune the polymeric properties.

Preparation of $\text{Mq}_n$-Functionalized Monomers

In one aspect the $\text{Mq}_n$-containing monomer typically includes two structural motifs: 1) a polymerizable unit or moiety that provides the required degree of control during the polymerization process; and 2) an $\text{Mq}_n$-moiety or residue, which typically comprises $\text{Mg}(II)$, $\text{Zn}(II)$, $\text{Al}(III)$, $\text{Ga}(III)$, or $\text{In}(III)$ coordinated with two or three, independently selected, 8-hydroxyquinoline-type residues, as disclosed herein. The term 8-hydroxyquinoline residue is used to refer to, among other things, an 8-hydroxyquinoline ligand that can be functionalized with at least one electron-donating group, at least one electron-withdrawing group, or a combination thereof; can be deprotonated; or can be not functionalized; and the like; or any combination of these. This term is also used to refer to 8-hydroxyquinoline-like ligands such as, for example, ligands in which either another heteroatom is present in one of the 6-membered rings of the 8-hydroxyquinoline ligand, or a partially hydrogenated 8-hydroxyquinoline-like ligand. Further, the $\text{Mq}_n$-containing monomer typically includes a third, optional, structural motif, namely: 3) an alkyl spacer between the polymerizable unit and the $\text{Mq}_n$, to decouple the backbone from the $\text{Mq}_n$ group.

In one aspect, norborene could be as the polymerizable unit. Norbornene can be polymerized using ring-opening metathesis polymerization (ROMP), a method that has a high tolerance to many functional groups. See, for example: Fürstner, A. Angew. Chem. Int. Ed. 2000, 39, 3012-3043; Piotti, M. E. Curr. Opin. Solid State Mater. Sci. 1999, 4, 539–547; Bielawski, C. W.; Grubbs, R. H. Angew. Chem. Int. Ed. 2000, 39, 2903–2906; and Sanford, M. S.; Ulman, M.; Grubbs, R. H. J. Am. Chem. Soc. 2001, 123, 749–750; each of which is incorporated herein by reference, in its entirety. Furthermore, ROMP is often a living polymerization method resulting in polymers with controlled molecular weights, low polydispersities, and also allows for the formation of block co-polymers. See also, for example: Ivin, K. J. Olefin Metathesis Academic Press: London, 1996; Ivin, K. J. and Mol, J. C. Olefin Metathesis and Metathesis Polymerization Academic Press: New York, 1997; each of which is incorporated herein by reference, in its entirety.
In one aspect, for example, the synthesis of a Mq,,-containing monomer encompasses the synthesis of a metal-free monomer as presented in Scheme 1, followed by metallating the monomer. As presented in Scheme 1 and in the Examples, this reaction sequence began with the functionalization of norborene to form bromomethyl norborene 1, formed using a Diels-Alder reaction between allyl bromide and cyclopentadiene. Attachment of a bromoalkyl chain using Grignard chemistry, followed by the conversion of the bromide to the nitrile and subsequent reduction of the nitrile, resulted in the precursor 4 in an overall yield of 51%. Compound 4 was then coupled to 6, itself prepared from compound 5 (8-hydroxyquinoline) as shown, followed by the reduction of the resulting imine to yield monomer 8. (See: Clemo, G. R.; Howe, R. J. Chem. Soc. 1955, 3552-3553; which is incorporated herein by reference in its entirety.)

As illustrated in Scheme 2, the formation of the Mq,,-functionalized monomer, such as the Alq,,-functionalized monomer 9 was achieved, for example, by adding monomer 8 to ten equivalents of triethylaluminum, followed by twenty equivalents of 8-hydroxyquinoline. This reaction resulted in the formation of one equivalent of 9 and nine equivalents of non-functionalized Alq,.. In one aspect, this procedure was developed to substantially achieve full metallation of each monomer without coordination of two monomer units onto the same aluminum center, thereby substantially preventing any cross-linking during the polymerization. The statistical probability of having two monomer units attached to the same aluminum center is 0.1%. While this number is negligible and no cross-linking was observed, a very small amount of cross-linking at this point could not be excluded.
Thus, in one aspect, this invention provides an $M_{q_1}$-functionalized compound comprising a polymerizable moiety and an $M_{q_2}$-moiety, wherein $q_1$ in each instance comprises an 8-hydroxyquinoline residue, and $M$ is selected from Mg, Zn, Al, Ga, or In; and $n$ is selected from 2 or 3, as the stoichiometry of the complex dictates based upon the valence of the metal.

In another aspect, this invention provides an $Al_{q_2}$-functionalized compound comprising a polymerizable moiety and an $Al_{q_3}$-moiety, wherein $q_2$ in each instance comprises an 8-hydroxyquinoline residue. In this aspect, the $Al_{q_3}$-moiety can be functionalized with at least one electron-donating group, at least one electron-withdrawing group, or a combination thereof, which can be used to tune the optical properties of the $Al_{q_3}$-functionalized compounds, monomers, and polymers. Thus, it is known that the usual blue-green luminescence of $Al_{q_3}$ can be either blue- or red-shifted through the addition of substituents to the 8-hydroxyquinoline residue.

In another aspect, the $M_{q_1}$-functionalized monomer can further comprise a chemical spacer between the polymerizable moiety and the $M_{q_2}$-moiety, and the chemical spacer can optionally be functionalized with at least one electron-donating group, at least one electron-withdrawing group, or a combination thereof. Thus, in one aspect, the chemical spacer comprises an alkyl linkage or spacer group, having between 1 and about 30 carbon atoms. In another aspect, the chemical spacer comprises an alkyl linkage or spacer group, having greater than or equal to about 4 carbon atoms. While not intending to be bound by theory, it is believed that this spacer was employed to assist in decoupling the motion of the backbone from the pendant $M_{q_2}$-moiety.

Also in this aspect, for example, the $M_{q_2}$-moiety can be functionalized with at least one group independently selected from: a hydrocarbyl group, an oxygen group, a sulfur group, a nitrogen group, a phosphorus group, an arsenic group, a carbon group, a silicon group, a germanium group, a tin group, a lead group, a boron group, an aluminum group, an inorganic group, an organometallic group, or a substituted analog thereof, any one of which having from 1 to about 30 carbon atoms; a halide; hydrogen; or any combination thereof, as long as these groups do not terminate the fluorescent properties of the resulting monomer and the resulting polymer. This list of possible substituents includes hydrogen, therefore the notion of a partially saturated analog or derivative of 8-hydroxyquinoline is encompassed by this invention. Further the substituents are independently selected, therefore, examples of these groups are provided below which are selected in each instance they appear in the functionalized $Al_{q_3}$-moiety, as long as these groups do not terminate the fluorescent properties of the resulting monomer and the resulting polymer.

Examples of each of these substituent groups include, but are not limited to, the following groups. In each example presented below, unless otherwise specified, $R$ is independently selected from: a hydrocarbyl group, an oxygen group, a sulfur group, a nitrogen group, a phosphorus group, an arsenic group, a carbon group, a silicon group, a germanium group, a tin group, a lead group, a boron group, an aluminum group, an inorganic group, an organometallic group, or a substituted analog thereof, any one of which having from 1 to about 30 carbon atoms; a halide; hydrogen; or any combination thereof. Thus, it is known that the usual blue-green luminescence of $Al_{q_3}$ can be either blue- or red-shifted through the addition of substituents to the 8-hydroxyquinoline residue.

Examples of hydrocarbyl groups include aliphatic groups which, in each instance, include, but are not limited to, an alkyl group, a cycloalkyl group, an alkenyl group, a cycloalkenyl group, an alkynyl group, an alkadienyl group, a cyclic group, and the like, and includes all substituted, unsubstituted, branched, and linear analogs thereof. For example, aliphatic groups as used herein include methyl, ethyl, propyl, n-butyl, tert-butyl, sec-butyl, isobutyl, amyl, isoamyl, hexyl, cyclohexyl, heptyl, octyl, nonyl, decyl, dodecyl, 2-ethylhexyl, pentenyl, butenyl, and the like.

Examples of hydrocarbyl groups also include aromatic groups which, in each instance, include, but are not limited to, a hydrocarbyl group, an oxygen group, a sulfur group, a nitrogen group, a phosphorus group, an arsenic group, a carbon group, a silicon group, a germanium group, a tin group, a lead group, a boron group, an aluminum group, an inorganic group, an organometallic group, or a substituted analog thereof, any one of which having from 1 to about 30 carbon atoms; a halide; hydrogen; or any combination thereof, as long as these groups do not terminate the fluorescent properties of the resulting monomer and the resulting polymer. This list of possible substituents includes hydrogen, therefore the notion of a partially saturated analog or derivative of 8-hydroxyquinoline is encompassed by this invention. Further the substituents are independently selected, therefore, examples of these groups are provided below which are selected in each instance they appear in the functionalized $Al_{q_3}$-moiety, as long as these groups do not terminate the fluorescent properties of the resulting monomer and the resulting polymer.

Examples of hydrocarbyl groups include aliphatic groups which, in each instance, include, but are not limited to, an alkyl group, a cycloalkyl group, an alkenyl group, a cycloalkenyl group, an alkynyl group, an alkadienyl group, a cyclic group, and the like, and includes all substituted, unsubstituted, branched, and linear analogs or derivatives thereof, in each instance having from one to about 30 carbon atoms. Thus, aliphatic groups include, but are not limited to, hydrocarbyls such as paraffins and alkenyls. For example, aliphatic groups as used herein include methyl, ethyl, propyl, n-butyl, tert-butyl, sec-butyl, isobutyl, amyl, isoamyl, hexyl, cyclohexyl, heptyl, octyl, nonyl, decyl, dodecyl, 2-ethylhexyl, pentenyl, butenyl, and the like.

Examples of hydrocarbyl groups also include aromatic groups which, in each instance, include, but are not limited to, a hydrocarbyl group, an oxygen group, a sulfur group, a nitrogen group, a phosphorus group, an arsenic group, a carbon group, a silicon group, a germanium group, a tin group, a lead group, a boron group, an aluminum group, an inorganic group, an organometallic group, or a substituted analog thereof, any one of which having from 1 to about 30 carbon atoms; a halide; hydrogen; or any combination thereof, as long as these groups do not terminate the fluorescent properties of the resulting monomer and the resulting polymer. This list of possible substituents includes hydrogen, therefore the notion of a partially saturated analog or derivative of 8-hydroxyquinoline is encompassed by this invention. Further the substituents are independently selected, therefore, examples of these groups are provided below which are selected in each instance they appear in the functionalized $Al_{q_3}$-moiety, as long as these groups do not terminate the fluorescent properties of the resulting monomer and the resulting polymer.
compounds include, but are not limited to, tolyl, xylyl, mesityl, and the like, including any heteroatom substituted derivative thereof.

Examples of hydrocarbyl groups further include cyclic organic groups which, in each instance, include, but are not limited to, cycloparaffins, cycloolefins, cycloacetylenes, aromatics such as phenyl, bicyclic groups and the like, including substituted derivatives thereof, in each instance having from about 3 to about 30 carbon atoms. Thus heteroatom-substituted cyclic groups such as furanyl are included herein.

In each instance, hydrocarbyl groups further include groups that contain both aliphatic and cyclic portions, examples of which include, but are not limited to, groups such as: -\((\text{CH}_2\text{)}_m\text{C}_6\text{H}_{10-q}\) wherein m is an integer from 1 to about 10, q is an integer from 1 to about 5, inclusive; (\(\text{CH}_2\text{)}_n\text{C}_6\text{H}_{10-q}\) wherein m is an integer from 1 to about 10, q is an integer from 1 to 10, inclusive; and (\(\text{CH}_2\text{)}_n\text{C}_6\text{H}_{10-q}\) wherein m is an integer from 1 to about 10, q is an integer from 1 to 10, inclusive. In each instance and as defined above, R is independently selected from: an aliphatic group; an aromatic group; a cyclic group; any combination thereof; any substituted derivative thereof; including but not limited to, a halide-, an alkoxide-, or an amide-substituted derivative thereof, any one of which has from 1 to about 30 carbon atoms; or hydrogen. In one aspect, aliphatic and cyclic groups include, but are not limited to: -\(\text{CH}_2\text{CH}_2\text{H}_2\); -\(\text{CH}_2\text{CH}_2\text{CH}_3\); -\(\text{CH}_2\text{CH}_2\text{Cl}\); -\(\text{CH}_3\text{CH}_2\text{Br}\); -\(\text{CH}_2\text{CH}_2\text{H}_2\); -\(\text{CH}_3\text{CH}_2\text{CH}_3\); -\(\text{CH}_2\text{CH}_2\text{H}_3\); -\(\text{CH}_3\text{CH}_2\text{CH}_2\text{F}\); -\(\text{CH}_2\text{CH}_2\text{CH}_2\text{Cl}\); -\(\text{CH}_2\text{CH}_2\text{CH}_2\text{Br}\); -\(\text{CH}_2\text{CH}_2\text{CH}_2\text{H}_2\); -\(\text{CH}_2\text{CH}_2\text{CH}_2\text{H}_3\); -\(\text{CH}_2\text{CH}_2\text{CH}_2\text{H}_4\); -\(\text{CH}_2\text{CH}_2\text{CH}_2\text{H}_5\); -\(\text{CH}_2\text{CH}_2\text{CH}_2\text{H}_6\); -\(\text{CH}_2\text{CH}_2\text{CH}_2\text{H}_7\); -\(\text{CH}_2\text{CH}_2\text{CH}_2\text{H}_8\); -\(\text{CH}_2\text{CH}_2\text{CH}_2\text{H}_9\); -\(\text{CH}_2\text{CH}_2\text{CH}_2\text{H}_{10}\); -\(\text{CH}_2\text{CH}_2\text{CH}_2\text{H}_{11}\); -\(\text{CH}_2\text{CH}_2\text{CH}_2\text{H}_{12}\); -\(\text{CH}_2\text{CH}_2\text{CH}_2\text{H}_{13}\); -\(\text{CH}_2\text{CH}_2\text{CH}_2\text{H}_{14}\); -\(\text{CH}_2\text{CH}_2\text{CH}_2\text{H}_{15}\); -\(\text{CH}_2\text{CH}_2\text{CH}_2\text{H}_{16}\); -\(\text{CH}_2\text{CH}_2\text{CH}_2\text{H}_{17}\); -\(\text{CH}_2\text{CH}_2\text{CH}_2\text{H}_{18}\); -\(\text{CH}_2\text{CH}_2\text{CH}_2\text{H}_{19}\); -\(\text{CH}_2\text{CH}_2\text{CH}_2\text{H}_{20}\); -\(\text{CH}_2\text{CH}_2\text{CH}_2\text{H}_{21}\); -\(\text{CH}_2\text{CH}_2\text{CH}_2\text{H}_{22}\); -\(\text{CH}_2\text{CH}_2\text{CH}_2\text{H}_{23}\); -\(\text{CH}_2\text{CH}_2\text{CH}_2\text{H}_{24}\); -\(\text{CH}_2\text{CH}_2\text{CH}_2\text{H}_{25}\); -\(\text{CH}_2\text{CH}_2\text{CH}_2\text{H}_{26}\); -\(\text{CH}_2\text{CH}_2\text{CH}_2\text{H}_{27}\); -\(\text{CH}_2\text{CH}_2\text{CH}_2\text{H}_{28}\); -\(\text{CH}_2\text{CH}_2\text{CH}_2\text{H}_{29}\); -\(\text{CH}_2\text{CH}_2\text{CH}_2\text{H}_{30}\).

Examples of halides, in each instance, include, but are not limited to, tolyl, xylyl, mesityl, and the like, including any heteroatom substituted derivative thereof.

In each instance, silicon groups are silicon-containing groups, which include, but are not limited to, dialkyl, dialkylarylsilyl groups, dialkylsilyl groups, dialkylaryl groups, and the like, which in each instance have from 1 to about 30 carbon atoms. Examples of silicon groups include, but are not limited to, trimethylsilyl and phenyltrimethylsilyl groups.

In each instance, germanium groups are germanium-containing groups, which include, but are not limited to, gemyl groups such as alkylgemyl groups, arylgemyl groups, arylalkylgemyl groups, gemylgermyl groups, and the like, which in each instance have from 1 to about 30 carbon atoms.

In each instance, tin groups include, but are not limited to, stannyl groups such as alkylstannyl groups, arylstannyl groups, arylalkylstannyl groups, and the like, which in each instance have from 1 to about 30 carbon atoms. Examples of tin groups include, but are not limited to, trimethylstannyl and phenyltrimethylstannyl groups.

In each instance, lead groups are lead-containing groups, which include, but are not limited to, alkyllead groups, aryllead groups, and the like, which in each instance have from 1 to about 30 carbon atoms. Examples of lead groups include, but are not limited to, trimethyllead and phenyltrimethyllead groups.

In each instance, boron groups are boron-containing groups, wherein R in each instance is selected from alkyl, cycloalkyl, aryl, alkaryl, substituted alkyl, or substituted aralkyl having from 1 to about 30 carbon atoms. Examples of boron groups include, but are not limited to, -\(\text{BR}_2\), -\(\text{BR}_{3}\), -\(\text{BR}_{4}\), -\(\text{BX}_2\), -\(\text{BX}_3\), -\(\text{BX}_4\), wherein X is a monomeric group such as halo, hydride, alkoxy, alkylthiolate, and the like, and wherein R in each instance is selected from alkyl, cycloalkyl, aryl, alkaryl, substituted alkyl, substituted aryl, or substituted aralkyl having from 1 to about 30 carbon atoms.

In each instance, phosphorus groups are phosphorus-containing groups, which include, but are not limited to, -\(\text{PR}_2\), -\(\text{PH}_2\), -\(\text{PO}(\text{OR})_2\), -\(\text{P}(\text{OR})_2\), -\(\text{P}(\text{O}(\text{OR})_2\) and the like, including substituted derivatives thereof, wherein R in each instance is selected from alkyl, cycloalkyl, aryl, alkaryl, substituted alkyl, substituted aryl, or substituted aralkyl having from 1 to about 30 carbon atoms.

In each instance, nitrogen groups are nitrogen-containing groups, which include, but are not limited to, -\(\text{NR}_2\), -\(\text{NHR}\), -\(\text{N}=\text{N}\), -\(\text{N}=-\text{N}\), -\(\text{N}=-\text{N}\), -\(\text{N}=-\text{N}\), and the like, including substituted derivatives thereof, wherein R in each instance is selected from alkyl, cycloalkyl, aryl, alkaryl, substituted alkyl, substituted aryl, or substituted aralkyl having from 1 to about 30 carbon atoms.

In each instance, oxygen groups are oxygen-containing groups, which include, but are not limited to, -\(\text{OR}\), -\(\text{O}(\text{OR})\), -\(\text{O}(\text{OR})_2\), -\(\text{O}(\text{OR})_3\), -\(\text{O}(\text{OR})_4\), -\(\text{O}(\text{OR})_5\), and the like, including substituted derivatives thereof, wherein R in each instance is selected from alkyl, cycloalkyl, aryl, alkaryl, substituted alkyl, substituted aryl, or substituted aralkyl having from 1 to about 30 carbon atoms. Examples of oxygen groups include, but are not limited to, trimethylsilyl and phenyloctylsilyl groups.
aryl, aralkyl, substituted alkyl, substituted aryl, or substituted aralkyl group or substituent on these ligands has from 1 to about 30 carbon atoms.

Examples of organometallic groups that may be used as substituents for substituted cyclopentadienyls, substituted indenyls, and substituted fluorenyls, in each instance, include, but are not limited to, organoborom groups, organoaluminum groups, organogallium groups, organosilicon groups, organogermainium groups, organotin groups, organolead groups, organo-transition metal groups, and the like, having from 1 to about 30 carbon atoms.

In another aspect, this invention provides an Mq-, functionalized compound comprising a polymerizable moiety and an Mq-, moiety, wherein q, in each instance, comprises an 8-hydroxyquinoline residue, and M is selected from Mg, Zn, Al, Ga, or In; and n is selected from 2 or 3, depending upon the valence of the metal. The Mq-, moiety can be functionalized with at least one electron-donating group, at least one electron-withdrawing group, or a combination thereof. In yet another aspect, Mq-, moiety can be functionalized with at least one group independently selected from: a hydrocarbyl group, an oxygen group, a sulfur group, a nitrogen group, a phosphorus group, an arsentic group, a carbon group, a silicon group, a germanium group, a tin group, a lead group, a boron group, an aluminum group, an inorganic group, an organometallic group, or a substituted analog thereof, any one of which having from 1 to about 30 carbon atoms; a halide; hydrogen; or any combination thereof.

In still another aspect, this invention provides an Mq,-functionalized compound comprising a polymerizable moiety and an Mq-, moiety, wherein q, in each instance, comprises an 8-hydroxyquinoline residue, and M is selected from Mg, Zn, Al, Ga, or In; and n is selected from 2 or 3 according to the valence of the metal, wherein the compound has the formula:

\[ \text{Y} \quad \text{Z} \quad n-1 \]
wherein \( n \) and \( m \) are independently selected from an integer from 0 to 3. Thus, this list of possible substituents includes hydrogen, therefore the notion of a partially saturated analog or derivative of 8-hydroxyquinoline is encompassed by this invention.

In yet another aspect, the present invention provides an Alq<sub>3</sub>-functionalized compound including, but not limited to:
In yet another aspect, the present invention provides an Mq₃-functionalized compound comprising a polymerizable moiety and an Mq₃-moiety, wherein the polymerizable moiety comprises norbornene, norbornadiene, cyclopentene, cyclooctene, cyclooctadiene, or a functionalized analog thereof. In yet another aspect, the polymerizable moiety comprises norbornene.

In still another aspect, the present invention provides an Mq₃-functionalized compound comprising a polymerizable moiety and an Mq₃-moiety, which further comprises a chemical spacer between the polymerizable moiety and the Mq₃-moiety, having between 1 and about 30 carbon atoms. In this aspect, for example, the chemical spacer is selected from —(CH2)ₙNR₁CH₂—, wherein n in the formula of the spacer is from 1 to about 12, and R₁ is selected from H or a hydrocarbyl or substituted hydrocarbyl having from 1 to about 30 carbon atoms. Thus, the chemical spacer can be —(CH2)ₙNHCH2—.

In still another aspect, this invention provides a light-emitting diode comprising the polymerization product of any Mq₃-functionalized compound disclosed herein.

Preparation of Mq₃-Functionalized Homo- and CoPolymers

The formation of the Alq₃-functionalized monomer 9 was achieved, for example, by adding monomer 8 to ten equivalents of triethylaluminum, followed by twenty equivalents of 8-hydroxyquinoline, as illustrated in Scheme 2 and in the Examples provided herein. This reaction resulted in the formation of one equivalent of 9 and nine equivalents of non-functionalized Alq₃. This 9:1 mixture (Alq₃:9) could be used directly in the polymerizations, which were carried out in chloroform at room temperature using the ruthenium catalyst 11. Under these conditions, a 50:1 monomer to catalyst ratio was fully polymerized to polymer 10 within 12 hours. After complete polymerization, the excess Alq₃ was removed from the polymer through extensive washings with methanol and methylene chloride, yielding a polymer without any impurities. The formation of the Znq₂-functionalized monomer was achieved similarly, using ZnEt₂ in place of AlEt₃ in Scheme 2.

The formation of the other Mq₃-functionalized monomers, wherein Mq₃ is selected from Mgq₂, Gaq₃, or Inq₃, may be achieved in a similar manner as that disclosed in Scheme 2, for example, by adding monomer 8 to an excess (about 10 equivalents) of metal halides, including, but not limited to, MgCl₂, GaCl₃, or InCl₃, respectively, followed by an excess (about twenty equivalents) of 8-hydroxyquinoline. Other halides such as bromides and iodides may be used as well. These Mq₃-functionalized monomers may then be polymerized as indicated in Scheme 2.

Solubility of the Alq₃-functionalized homopolymer proved to be limited, and redissolving the polymer proved to be difficult, possibly due to the highly charged character of the polymer. However, solubility of the Alq₃-functionalized polymer could be increased by co-polymerizing 9 with 5-nonylnorbornene 12, a non-functionalized monomer, which was synthesized as shown in Scheme 3, and presented in the Examples.
Using comonomers such as compound 12, Alq₃-functionalized copolymers could be prepared according to Scheme 4. Znq₂-functionalized copolymers could be prepared similarly, according to Scheme 4. The other Mqₙ-functionalized copolymers can also be polymerized as indicated in Scheme 4 for the Alq₃ system. Thus, in this aspect, solubility of the Alq₃-functionalized copolymer exceeded that of the Alq₃-functionalized homopolymer. However, in one aspect, this invention provides for the formation of an Alq₃-functionalized copolymer, wherein the molar ratio of the functional monomer to spacer monomer is from about 1,000:1 to about 1:1,000. In another aspect, the molar ratio of the functional monomer to spacer monomer is from about 1:1 to about 1:100, and in another aspect, from about 1:3 to about 1:20. In yet another aspect, the molar ratio of the functional monomer to spacer monomer is from about 1:4 to about 1:10.

In another aspect, the molar ratio of functional monomer to spacer monomer (9:12) was examined to determine ratios...
wherein 9 can be incorporated in a relatively high percentage, while retaining a useful measure of solubility. This ratio was investigated through the synthesis of a series of copolymers, as illustrated in Table 1. All copolymers with a 9:12 ratio of at least about 1:1 could be fully solubilized in a 0.1% (v/v) chloroform/triethanolamine acid mixture. All resolubilized co-polymers were characterized using gel-permeation chromatography and showed polydispersities from about 1.5 to about 1.8. Differential scanning calorimetry did not show a glass-transition temperature or a melting temperature for these copolymers, while thermogravimetric analysis showed the onset of polymer decomposition at 250°C.

In one aspect, this invention provides a composition comprising the polymerization product of an Mq,-functionalized monomer, wherein the Mq,-functionalized monomer comprises a polymerizable moiety and an Mq,-moiety, wherein q, in each instance, comprises an 8-hydroxyquinoline residue; M is selected from Mg, Zn, Al, Ga, or In; and n is selected from 2 or 3 according to the valence of the metal. In another aspect, the polymerization product can be substantially non-cross-linked. Further, and in another aspect, the Mq,-moiety can be functionalized with at least one electron-donating group, at least one electron-withdrawing group, or a combination thereof. In another aspect, the polymerizable moiety can comprise norborne. This invention further provides a light-emitting diode comprising the polymerization product of an Mq,-functionalized monomer, wherein the Mq,-functionalized monomer comprises a polymerizable moiety and an Mq,-moiety, wherein q, in each instance, comprises an 8-hydroxyquinoline residue; M is selected from Mg, Zn, Al, Ga, or In; and n is selected from 2 or 3.

In yet another aspect of this invention, this invention provides a composition comprising the polymerization product of at least one Mq,-functionalized monomer and at least one comonomer, wherein the Mq,-functionalized monomer comprises a polymerizable moiety and an Mq,-moiety, wherein q, in each instance, comprises an 8-hydroxyquinoline residue; M is selected from Mg, Zn, Al, Ga, or In; and n is selected from 2 or 3 according to the valence of the metal. In another aspect, the polymerizable moiety can comprise norborne, norbornadiene, cyclopentene, cyclooctene, cyclooctadiene, or a substituted analog thereof. In yet another aspect, the polymerizable moiety can comprise norborne or a substituted analog thereof.

In yet another aspect, this invention provides a composition comprising the polymerization product of at least one Mq,-functionalized monomer and at least one comonomer, wherein the Mq,-functionalized monomer comprises a polymerizable moiety and an Mq,-moiety, wherein the Mq,-moiety can be functionalized with at least one electron-donating group, at least one electron-withdrawing group, or a combination thereof. In another aspect, the Mq,-moiety can be functionalized with at least one group independently selected from: a hydrocarbyl group, an oxygen group, a sulfur group, a nitrogen group, a phosphorus group, an arsenic group, a carbon group, a silicon group, a germanium group, a tin group, a lead group, a boron group, an aluminum group, an inorganic group, an organometallic group, or a substituted analog thereof; any one of which having from 1 to about 30 carbon atoms; a halide; hydrogen; or any combination thereof.
Ph, or a substituted analog thereof, any one of which having up to about 30 carbon atoms.

In still another aspect, this invention provides an Mq, functionalized monomer comprising a polymerizable moiety and an Mq, moiety, wherein q, in each instance, comprises an 8-hydroxyquinoline residue, and wherein the Mq, functionalized monomer further comprises a chemical spacer between the polymerizable moiety and the Mq, moiety, having between 1 and about 30 carbon atoms. In this formula, M is selected from Mg, Zn, Al, Ga, or In; and n is selected from 2 or 3 as dictated by the valence of the metal.

Also in this aspect, this invention further provides a composition comprising the polymerization product of at least one Mq, functionalized monomer and at least one comonomer, wherein the Mq, functionalized monomer comprises a polymerizable moiety and an Mq, moiety, and wherein the Mq, functionalized monomer further comprises a chemical spacer between the polymerizable moiety and the Mq, moiety, having between 1 and about 30 carbon atoms. In one aspect, the chemical spacer can be selected from -(CH2)nNHCH2- or -(CH2)nNR2CH2-, wherein n in the formula of the spacer is from 1 to about 12, and R1 is selected from a hydrocarbyl or substituted hydrocarbyl having from 1 to about 30 carbon atoms.

In a further aspect, this invention provides the polymerization product of at least one Mq, functionalized monomer and at least one comonomer, wherein the polymerization product comprises a block copolymer. This invention provides the polymerization product of at least one Mq, functionalized monomer and at least one comonomer, wherein the polymerization product comprises a random copolymer.

In still a further aspect, this invention provides a composition comprising the polymerization product of at least one Alq3-functionalized monomer and at least one comonomer, wherein the Alq3-functionalized monomer comprises a polymerizable moiety and an Alq3-moiety, and wherein q, in each instance, comprises an 8-hydroxyquinoline residue, wherein the Alq3-functionalized monomer can be selected from:
any combination thereof. In another aspect, the at least one comonomer can comprise a compound with the formula

wherein \( n \) is an integer from 1 to about 12.

In a further aspect, this invention provides a composition comprising the polymerization product of at least one Alq3-functionalized monomer and at least one comonomer, wherein the Alq3-functionalized monomer comprises a polymerizable moiety and an Alq3-moiety, and wherein the polymerization product can be characterized by a polydispersity (Mw/Mn) from about 1.5 to about 1.8. In another aspect, this invention provides a light-emitting diode comprising the polymerization product of at least one Alq3-functionalized monomer and at least one comonomer, wherein the Alq3-functionalized monomer comprises a polymerizable moiety and an Alq3-moiety.

In still a further aspect, this invention provides a method of making an Mq,,-functionalized polymer, comprising:

- polymerizing an Mq,,-functionalized monomer in the presence or absence of at least one comonomer;
- wherein the Mq,,-functionalized monomer comprises a polymerizable moiety and an Mq,,-moiety; and
- wherein q, in each instance, comprises an 8-hydroxyquinoline residue; M is selected from Mg, Zn, Al, Ga, or In; and \( n \) is selected from 2 or 3 as dictated by the valence of the metal. In another aspect, the Mq,,-functionalized monomer can be polymerized in the presence of at least one comonomer. In this aspect, in the method disclosed herein, the Mq,,-functionalized monomer can be polymerized in the presence of at least one comonomer, and wherein the molar ratio of Mq,,-functionalized monomer to comonomer is from about 1:1 to about 1:20. Also in this aspect, the Mq,,-functionalized monomer can be polymerized in the presence of at least one comonomer comprising

wherein \( n \) is an integer from 1 to about 12.

In another aspect, this invention provides a method of making an Mq,,-functionalized polymer, comprising:

- polymerizing an Mq,,-functionalized monomer in the presence or absence of at least one comonomer;
- wherein the Mq,,-functionalized monomer comprises a polymerizable moiety and an Mq,,-moiety; and
- wherein the polymerizable moiety of the Mq,,-functionalized monomer can be selected from norbornene, norbornadiene, cyclopentene, cyclooctene, cyclooctadiene, or a functionalized analog thereof. In this aspect, the method of making an Mq,,-

In still another aspect, the present invention provides a method of making an Mq,,-functionalized polymer comprising polymerizing an Mq,,-functionalized monomer in the presence or absence of at least one comonomer, wherein the polymerization can be conducted in the presence of a catalyst comprising a transition metal carbene compound. In this aspect, the polymerization can be conducted in the presence of any ring-opening metathesis polymerization (ROMP) catalyst, as long as the monomers, functional groups, or conditions required for polymerization do not terminate the activity of the catalyst. In this aspect, the polymerization can be conducted in the presence of Grubbs’ catalysts such as Ru(CPh)Cl2(CH2Cl)2C6H4 (PCy3)11 as shown in the reaction schemes.

In still another aspect, the present invention provides a method of making an Mq,,-functionalized polymer comprising polymerizing an Mq,,-functionalized monomer in the presence or absence of at least one comonomer, wherein the Mq,,-moiety of the Mq,,-functionalized monomer can be functionalized with at least one group independently selected from: a hydrocarbyl group, an oxygen group, a sulfur group, a nitrogen group, a phosphorus group, an amino group, a hydroxy group, an alkoxy group, a thio group, a thiophenyl group, an alkenyl group, an alkynyl group, a halogen group, a silyl group, a substituted analog thereof, any one of which having from 1 to about 30 carbon atoms; and wherein any one of which having up to about 30 carbon atoms.

In another aspect, this invention provides a method of making an Alq3,-functionalized polymer comprising polymerizing an Alq3,-functionalized monomer in the presence or absence of at least one comonomer, wherein the Alq3,-moiety of the Alq3,-functionalized monomer can be functionalized with at least one group independently selected from methyl, ethyl, propyl, cyclopropyl, n-butyl, tert-butyl, sec-butyl, isobutyl, cyclobutyl, amyl, isoamyl, pentyl, cyclopentyl, hexyl, cyclohexyl, cyclooctyl, heptyl, octyl, cyclooctyl, nonyl, decyl, dodecyl, 2-ethylhexyl, pentenyl, butenyl, benzy1, phenyl, tolyl, naphthyl, anthracenyl, F, Cl, Br, I, OR, OEt, O-n-Pr, O-i-Pr, O-n-Bu, O-t-Bu, O-s-Bu, OPPh, OC6H4Me, OC6H4Me2, NMe2, NET3, NHMe, NHeI, NHPh, —CH=O, —CH=CH(O)Ph, or a substituted analog thereof, any one of which having to about 30 carbon atoms.

In another aspect, this invention provides a method of making an Alq3,-functionalized polymer comprising polymerizing an Alq3,-functionalized monomer in the presence or absence of at least one comonomer, wherein the Alq3,-moiety of the Alq3,-functionalized monomer can be functionalized with at least one group independently selected from methyl, ethyl, propyl, cyclopropyl, n-butyl, tert-butyl, sec-butyl, isobutyl, cyclobutyl, amyl, isoamyl, pentyl, cyclopentyl, hexyl, cyclohexyl, cyclooctyl, heptyl, octyl, cyclooctyl, nonyl, decyl, dodecyl, 2-ethylhexyl, pentenyl, butenyl, benzy1, phenyl, tolyl, naphthyl, anthracenyl, F, Cl, Br, I, OR, OEt, O-n-Pr, O-i-Pr, O-n-Bu, O-t-Bu, O-s-Bu, OPPh, OC6H4Me, OC6H4Me2, NMe2, NET3, NHMe, NHeI, NHPh, —CH=O, —CH=CH(O)Ph, or a substituted analog thereof, any one of which having up to about 30 carbon atoms.

In another aspect, this invention provides a method of making an Alq3,-functionalized polymer comprising polymerizing an Alq3,-functionalized monomer in the presence or absence of at least one comonomer, wherein the Alq3,-moiety of the Alq3,-functionalized monomer can be functionalized with at least one group independently selected from methyl, ethyl, propyl, cyclopropyl, n-butyl, tert-butyl, sec-butyl, isobutyl, cyclobutyl, amyl, isoamyl, pentyl, cyclopentyl, hexyl, cyclohexyl, cyclooctyl, heptyl, octyl, cyclooctyl, nonyl, decyl, dodecyl, 2-ethylhexyl, pentenyl, butenyl, benzy1, phenyl, tolyl, naphthyl, anthracenyl, F, Cl, Br, I, OR, OEt, O-n-Pr, O-i-Pr, O-n-Bu, O-t-Bu, O-s-Bu, OPPh, OC6H4Me, OC6H4Me2, NMe2, NET3, NHMe, NHeI, NHPh, —CH=O, —CH=CH(O)Ph, or a substituted analog thereof, any one of which having up to about 30 carbon atoms.

In another aspect, this invention provides a method of making an Alq3,-functionalized polymer comprising polymerizing an Alq3,-functionalized monomer in the presence or absence of at least one comonomer, wherein the Alq3,-moiety of the Alq3,-functionalized monomer can be functionalized with at least one group independently selected from methyl, ethyl, propyl, cyclopropyl, n-butyl, tert-butyl, sec-butyl, isobutyl, cyclobutyl, amyl, isoamyl, pentyl, cyclopentyl, hexyl, cyclohexyl, cyclooctyl, heptyl, octyl, cyclooctyl, nonyl, decyl, dodecyl, 2-ethylhexyl, pentenyl, butenyl, benzy1, phenyl, tolyl, naphthyl, anthracenyl, F, Cl, Br, I, OR, OEt, O-n-Pr, O-i-Pr, O-n-Bu, O-t-Bu, O-s-Bu, OPPh, OC6H4Me, OC6H4Me2, NMe2, NET3, NHMe, NHeI, NHPh, —CH=O, —CH=CH(O)Ph, or a substituted analog thereof, any one of which having up to about 30 carbon atoms.
The emission spectra of Alq3 and the copolymers were collected from 400-700 nm, with an excitation wavelength of 380 nm. FIG. 2 illustrates the emission spectra of Alq3 and the series of 9:12 copolymers in CHCl3 solution, excited at 380 nm, as described in Table 1. As shown in FIG. 2, all copolymers fluoresce at the same wavelength as Alq3 in solution, demonstrating that the emission properties of Alq3 are retained in the polymer matrix.

The ratio of Alq3-monomer to the non-functionalized monomer in the copolymers affected the intensity of the emission. Thus the intensity showed a linear relationship with the percentage of Alq3 present in the copolymer, as indicated by the data provided in Table 1. While not intending to be bound by theory, these studies suggest that the optical properties of Alq3 are preserved in the polymer and not affected by the polymer coil while in solution. Upon spin-casted the copolymer solutions to provide thin films of the Alq3-functionalized polymer, the resulting films exhibited fluorescence emission similar to that of Alq3 in the solid state. Table 2 provides absorption and photoluminescence data for 9, Alq3, and a series of co-polymers recorded on relatively dilute solutions, as compared to the data recorded in Table 1.

While not intending to be bound by theory, when comparing Alq3-functionalized polymers to the other Mq3-functionalized polymers, fluorescence is generally expected to be reduced with increasing atomic number of the metal ion, which is referred to as the heavy atom effect. In addition, as the covalent bond character between metal and quinoline ligand increases, the Mq3 complexes are expected to become more red shifted. For example, and again while not intending to be bound by theory, the analogous Al, Ga, and In complexes would be expected to emit at progressively longer wavelengths (red shifted). See, for example: Chen, C. H.; Shi, J. Coord. Chem. Rev. 1998, 171, 161-174, which is incorporated herein by reference in its entirety.

Preparation of Selected Mq3-Functionalized Polymers With an Electronically-Tuned Ligand Sphere

Another aspect of this invention is an Mq3-functionalized polymer with an electronically-tuned ligand sphere about the metal center. In this aspect, this invention provides a composition comprising the polymerization product of an Mq3-functionalized monomer, wherein the Mq3-functionalized monomer can comprise a polymerizable moiety and an Mq3-moiety, wherein q, in each instance, comprises an 8-hydroxyquinoline residue, and M is selected from Mg, Zn, Al, Ga, or In; and n is selected from 2 or 3 according to the valence of the metal. Further to this aspect, this invention

The UV/Visible absorption spectrum of monomer 9 shows a $\lambda_{\text{max}}$ at 319 nm, corresponding to the low-energy singlet transition of the hydroxyquinoline group. (See: Ravi Kishore, V. V. N.; Aziz, A.; Narasimhan, K. L.; Periasamy, N.; Meenakshi, P. S.; Wategaonkar, S. Synth. Met. 2002, 126, 199-205, which is incorporated by reference herein in its entirety.) The absorption spectrum of Alq3 showed peaks at 372 nm and at 316 nm, consistent with the reported spectrum. (See: Hall, M. D.; Schlegel, H. B. Chem. Mater. 2001, 13, 2632-2640, which is incorporated by reference herein, in its entirety.) FIG. 1 illustrates the UV/Visible absorption spectra of Alq3, the Alq3-containing monomer 9, and the series of 9:12 copolymers in CHCl3 solution, as described in Table 1. The absorption spectra of all the copolymers examined showed identical peaks as that of Alq3, indicating the same transitions taking place in the copolymer system as the ones known for Alq3. Absorption and photoluminescence data for 9, Alq3, and a series of co-polymers recorded on relatively dilute solutions are presented in Table 2, as compared to the data recorded in Table 1.

The emission spectra of Alq3 and the copolymers were collected from 400-700 nm, with an excitation wavelength of 380 nm. FIG. 2 illustrates the emission spectra of Alq3 and the series of 9:12 copolymers in CHCl3 solution, excited at 380 nm, as described in Table 1. As shown in FIG. 2, all copolymers fluoresce at the same wavelength as Alq3 in solution, demonstrating that the emission properties of Alq3 are retained in the polymer matrix.

In yet another aspect, the present invention provides a method of functionalizing a polymer with an Alq3 moiety, comprising:

- providing an Alq3-functionalized monomer; and
- polymerizing an Alq3-functionalized monomer in the presence or absence of at least one comonomer;

wherein the Alq3-functionalized monomer comprises a polymerizable moiety and an Alq3-moiety; and

wherein q, in each instance, comprises an 8-hydroxyquinoline residue.

**Optical Properties of Selected Mq3-Functionalized Polymers**

The photoluminescence of the Alq3-functionalized copolymers and monomer 9 were investigated and compared to the photoluminescence of Alq3 itself. As a measure of the baseline performance of the copolymers and monomer 9, commercial Alq3 was treated with the same chloroform/trifluoroacetic acid mixture as the copolymers. No changes were detected in the optical properties of Alq3 after this treatment, as compared to the optical properties of Alq3 before this treatment.

The ratio of Alq3-monomer to the non-functionalized monomer in the copolymers affected the intensity of the emission. Thus the intensity showed a linear relationship with the percentage of Alq3 present in the copolymer, as indicated by the data provided in Table 1. While not intending to be bound by theory, these studies suggest that the optical properties of Alq3 are preserved in the polymer and not affected by the polymer coil while in solution. Upon spin-casted the copolymer solutions to provide thin films of the Alq3-functionalized polymer, the resulting films exhibited fluorescence emission similar to that of Alq3 in the solid state. Table 2 provides absorption and photoluminescence data for 9, Alq3, and a series of co-polymers recorded on relatively dilute solutions, as compared to the data recorded in Table 1.

**Preparation of Selected Mq3-Functionalized Polymers With an Electronically-Tuned Ligand Sphere**

Another aspect of this invention is an Mq3-functionalized polymer with an electronically-tuned ligand sphere about the metal center. In this aspect, this invention provides a composition comprising the polymerization product of an Mq3-functionalized monomer, wherein the Mq3-functionalized monomer can comprise a polymerizable moiety and an Mq3-moiet, wherein q, in each instance, comprises an 8-hydroxyquinoline residue, and M is selected from Mg, Zn, Al, Ga, or In; and n is selected from 2 or 3 according to the valence of the metal. Further to this aspect, this invention...
provides a composition comprising the polymerization product of an Alq$_3$-functionalized monomer, which can comprise a polymerizable moiety and an Alq$_3$-moiety, and wherein $q$, in each instance, comprises an 8-hydroxyquinoline residue, which, in accordance with this invention, can include a residue of an 8-hydroxyquinoline-like compound, or a functionalized analog of an an 8-hydroxyquinoline or an 8-hydroxyquinoline-like compound. Further in this aspect, the Alq$_3$-moiety of the Alq$_3$-functionalized monomer can be functionalized with at least one electron-donating group, at least one electron-withdrawing group, or a combination thereof. For example, the ligand sphere around the aluminum center on the polymer can be functionalized with electron-donating or withdrawing groups thereby allowing the emission of the polymer to be tuned from blue to yellow (from about 430 nm to about 549 nm).

In one aspect, this invention provides the ability to tune the emission of the Alq$_3$-functionalized monomer, and hence the Alq$_3$-functionalized polymer, according to the functionalization of the ligand sphere around the aluminum center on the polymer with electron-donating, withdrawing groups, or a combination thereof.

In one aspect, this invention provides for the modification of the 8-hydroxyquinoline ligand with electron-donating or withdrawing groups, or by the introduction of heteroatoms. A large number of these functionalized 8-hydroxyquinoline molecules are commercially available from, for example, Labo Test (Niederschönau, Germany) and can be used in this invention.

The synthesis of the modified Alq$_3$-functionalized monomers is shown in Scheme 5, in which the 8-hydroxyquinoline ring system is modified with electron-donating or withdrawing groups, or by the introduction of heteroatoms into the 8-hydroxyquinoline ring system. The structures of the resulting monomers are illustrated in Table 3. The functionalized 8-hydroxyquinoline ligands employed in this Scheme, represented by “X”, are shown in FIG. 3, along with the abbreviations used to designate these ligands. Thus, as illustrated in Scheme 5, the typical modified Alq$_3$-containing monomer has one 8-hydroxyquinoline ligand coordinating the aluminum that derived from the polymerizable molecule comprising a norbornene moiety, while the other two 8-hydroxyquinoline ligands constitute the 8-hydroxyquinoline ring systems that are modified with electron-donating or withdrawing groups, or by the introduction of heteroatoms. A large number of these functionalized 8-hydroxyquinoline molecules are commercially available from, for example, Labo Test (Niederschönau, Germany) and can be used in this invention.

As illustrated in Scheme 5 and in the Examples, metalation of monomer 3 was carried out by the addition of 8 to a solution of triethylaluminum, resulting in the formation of the metallated monomer 14. The addition of two equivalents of the modified 8-hydroxyquinoline ligands X to monomer 14 resulted in the formation of monomers 15a-15j (referred to generically as 15) in quantitative yields. Examples of the functionalized 8-hydroxyquinoline ligands include, but are not limited to, those ligands shown in FIG. 3 and Table 3.

Scheme 6 illustrates that polymerizations were carried out by combining 12 and 15 in chloroform and adding catalyst 11. Thus, co-polymerization with nonylnorbornene was employed to render all polymers highly soluble in common organic solvents. In one aspect, a molar ratio of AlqX₂:monomer to nonylnorbornene of about 1:20 was used in all fluorescence studies unless otherwise noted, which provided good results.

Scheme 6
In still another aspect, this invention provides for the use of a variety of polymerizable moieties other than norborene to be used in the preparation of the Mq,-functionalized monomers and the Mq,-functionalized polymers. In one aspect, for example, the preparation of an Alq3-functionalized monomer, comprising a cyclooctene polymerizable moiety, is presented in Scheme 7. The preparation provided in Scheme 7 is applicable to the range of Mq,-functionalized monomers and the Mq,-functionalized polymers.
In still another aspect, this invention provides for the preparation of zinc-containing monomers and polymers, as illustrated in Scheme 8. Thus, Scheme 8 illustrates that polymerizations were carried out by combining 12 and 17 in solution and adding catalyst 11. Thus, co-polymerization with nonylnorbomene was employed to render all polymers highly soluble in common organic solvents. In one aspect, a molar ratio of ZnQ₃-monomer or ZnQX-monomer to nonyl-norbomene of about 1:20 was used in all fluorescence studies unless otherwise noted, which provided good results. As in the aluminum compounds, the design, synthesis, and characterization of the ZnQ₃-copolymers, demonstrated excellent photoluminescence properties, with emission wavelengths ranging from the blue to the yellow, while retaining the solution processability. Accordingly, these copolymers could be used in electroluminescent devices.

To examine and improve solubilities, monomer 8 was co-polymerized with a spacer monomer, nonyl-norbomene 12, in ratios of 1:1, 1:5, 1:10, and 1:20 (8/12), resulting in copolymers that were readily soluble. The 1:20 ratios were used to characterize the optical properties of the copolymers, unless otherwise noted.
Chemical, Physical, and Optical Properties of Alq₃-Functionalized Polymers With an Electronically-Tuned Ligand Sphere

The Alq₃-functionalized polymers with electronically-tuned ligand spheres were characterized by NMR, gel-permeation chromatography (GPC), differential scanning calorimetry (DSC), and thermogravimetric analysis (TGA), with the results summarized in Table 4. The polymerizations were followed by NMR and were considered complete when no olefin signals were detected. In one aspect, the molecular weights of the polymers, determined by GPC, ranged from about 7000 to about 55000, with polydispersities (PDI) from about 1.26 to about 2.74. All polymers showed a decompo-
Solution Fluorescence Studies on Alq₃ Complexes

The normalized solution emission spectra of selected modified polymers in chloroform are presented in FIG. 4. Solution emission results are also summarized in Table 5. The unmodified Alq₃-polymer (Alq₃) was observed to emit at the same wavelength as pure Alq₃ (523 nm). Similar to modified-Alq₃, the polymers containing functionalized Alq₃ side-chains show either a blue- or red-shifted emission, depending on the functionalization. While most of the modified 8-hydroxyquinoline ligands induce shifts in the emission spectra, the most noticeable shifts result from polymers functionalized with either the 4-hydroxy-1,5-naphthyridine (Naph) or the quinoxalinol (Quinox) ligands. The naphthyridine ligand induces a strong blue-shifted of about 50 nm, while the quinoxalinol ligand induces a red-shifted of about 50 nm. Other dramatic shifts occurred after functionalization with the aldehyde-functionalized ligand (CHO) (~32 nm) and the phenyl-vinyl-ketone-functionalized ligand (PVK) (~212 nm).

°Polymers are named after the functionalized ligand X; all polymers comprise a 1:20 ratio of 15:12. 1:20 ratio.

°Polymera and 1000mer refer to the number of repeat units in the polymer.

The emission spectrum of the Naph-polymer shows two maxima, one at 430 nm and the other one at 490 nm. The two maxima can be attributed to the two different ligands: one from the aluminum center, namely, two naphthyridine ligands and one hydroxyquinoline ligand. Again, while not intending to be bound by theory, it is likely that the peak at 430 nm arises from an oriented naphthyridine ligand, while the emission peak at 490 nm arises from the hydroxyquinoline ligand. The electronics of the hydroxyquinoline ligand are affected by the naphthyridine ligand, resulting in a blue-shift from the usual 520 nm. This idea was tested by preparing the small molecule counterpart containing two naphthyridine ligands and a hydroxyquinoline ligand around an aluminum center. The emission spectrum of this compound was identical to that of the polymer. This two ligand effect can also be seen in the CHO-polymer, with a small shoulder occurring at 450 nm.

These data from the solution emission studies suggest that the polymer backbone does not interfere with the optical properties of the Alq₃ side-chain, and that the emission can be tuned through simple ligand modifications.

Thus, in one aspect of this invention, using electron-donating or electron-withdrawing ligands that can shift the emission wavelength, perhaps because the donating or electron-withdrawing ability of the substituents on the modified ligands.

Thin-Film Characterization of Alq₃-Containing Polymers

Thin films of the functionalized Alq₃-containing polymers were fabricated by spin coating techniques and were characterized using optical microscopy, ellipsometry, and fluorescence spectroscopy. The thicknesses of the films ranged from about 200 nm to about 600 nm depending on the concentration of the polymer solution. The uniformity of the films was observed using an inverted microscope while irradiating the films with UV light. These observations indicated that all of the films showed very smooth surfaces with good uniformity and very few defects.

Experiments were conducted to determine if the functionalized Alq₃-containing polymers could support a current. Thin films of 1:1, 1:10, and 1:20 Alq₃-copolymers were...
characterized. All three films were conductive, with the conductivity ranging between 4–12 S/cm and the highest conductivity for the 1:5 Alq₃ copolymer, as shown in Table 6. This observation suggests that the polymer system of this invention can be used as the electron-transport and emission layer in OLEDs.

*Polymers are named after the functionalized ligand X and the ratio of 15:12. For example, Alq₃ 110 is a 1:10 molar ratio of compound 15:12, wherein the ligand is Alq₃.

Solid-State Fluorescence Studies of Alq₃-Functionalyzed Polymers

The optical properties of all Alq₃-functionalyzed polymers were also investigated in the solid-state. Unless otherwise noted, all polymers were excited at 380 nm (except for the Naph- and Quinox-polymers, which were excited at 350 nm and 400 nm, respectively) and their emission data are shown in Table 7. FIG. 5 shows the normalized fluorescence spectra of selected polymers as thin films on quartz. In the case of each functionalized polymer observed, spectra were observed to show shifts in the emission compared to the unmodified Alq₃-polymer. However, in all cases, the shifts were not as pronounced as the shifts observed for the same polymer in solution. Furthermore, under the conditions employed, the Nitro-, Quinox-, and Phenyl-polymers showed no emission at all. Nevertheless, the observed shifts demonstrate that tuning the emission color is possible and that the polymer backbone does not inhibit fluorescence even in the solid-state.

*Polymers are named after the functionalized ligand X and the molar ratio of 15:12. For example, Alq₃110 is a 1:10 molar ratio of compound 15:12, wherein the ligand is Alq₃.

In order to investigate the influence of chromophore density on the emission, the ratio of the AlqX₂-monomer and nonylnorbornene was varied. The results of this study are shown in FIGS. 6–8 and are summarized in Table 7. FIG. 6 illustrates the solid-state fluorescence spectra of the Alq₃-polymer with functionalyzed Alq₃-monomer (15) to nonylnorbornene (12) ratios of 1:10, 1:20, and 1:50. The emission wavelength is observed to be blue-shifted with decreasing chromophore density. Similar results can also be seen in FIG. 7 for the CH-polymer and FIG. 8 for the PVK-polymer. While the shifts are different for each polymer, the trend is the same in all cases. However, a 1:100 ratio of 15:12 of the CH-polymer showed identical emission peaks as that of the 1:50 CH-polymer, therefore, this chromophore dilution effect appeared to be limited. While not intending to be bound by theory, this observation suggested that the emission wavelength is dependant on the packing of the AlqX₂-complex, which is consistent with the notion that the shorter the inter-ligand contacts, the more red-shifted the emission. (See, Brinkmann, M.; Gredtet, G.; Muccini, M.; Taliani, C.; Masciocchi, N.; Sirani, A. J. Am. Chem. Soc. 2000, 122, 5147–5157, which is incorporated by reference herein in its entirety.)

The effect of molecular weight on the optical properties was also investigated. As shown in Table 5, it was found that the changes in molecular weight have very little effect on the emission of the polymer, both in solution and the solid-state. FIG. 9 provides examples of catalysts that can be used for polymerizing the functionalyzed monomers to the functionalyzed polymers, based on a ring-opening metathesis polymerization (ROMP) catalytic process.

Fluorescence Studies on Znq₂ Complexes

All zinc-containing copolymers 18 were characterized using NMR, UV/Vis, and fluorescence spectroscopy, with the results being summarized in Table 8. The molecular weights of the copolymers ranged from about 8,000 to about 40,000, with polydispersities from about 1.5 and about 2.5 as determined by GPC. The UV/Vis and Fluorescence spectra were recorded in dry chloroform. FIG. 10 illustrates the solution fluorescence spectra of all Znq₂-functionalyzed copolymers, excited at 380 nm, except for the Naph copolymer which was excited at 330 nm. FIG. 11 demonstrates that the emission of the Znq₂-functionalyzed copolymers can be tuned in solution from blue (427 nm) to the yellow (565 nm) through modifications on the second functionalyzed quinoline. These results further demonstrate that the fluorescence properties of the material can be tuned in solution and that the polymer backbone does not interfere with the optical properties of the Znq₂ moiety.

The relative quantum yields of the zinc-containing copolymers 18 were calculated based on Alq₃ as the standard and are summarized in Table 8. Znq₂-containing monomer was observed to have a higher quantum yield than Alq₃. The 1:1, 1:5, and 1:10 Znq₂-copolymers were observed to exhibit even higher quantum yields than their small molecule counterpart. It is not until the concentration of the Znq₂-monomer dropped below about 10 mol% of the copolymer that the quantum yields decrease below that of Znq₂. While not intending to be bound by theory, the increase in quantum yields going from Znq₂ to the 1:1 Znq₂-copolymer to the 1:5 Znq₂-copolymer indicates the possibility of some self-quenching occurring at higher Znq₂ concentrations.

To characterize the solid-state properties of all ZnQ_2-containing copolymers, thin films were spun on quartz slides, with thicknesses ranging between 200-400 nm as determined by ellipsometry. The fluorescence spectra were recorded at an excitation wavelength of 380 nm (Naph at 330 nm) and are shown in FIG. 11, with the A_{max} reported in Table 8. Similar to the solution studies, the emission colors of the films range from the blue to the yellow. The influence of the lumophore density on the solid-state properties was also investigated. The 1:1 copolymer emission, a high lumophore concentration, is red-shifted in comparison to the emission of the 1:20 copolymer. Regardless of the lumophore concentration and the quinoline ligand used, the emission of the thin films again indicated that the polymer backbone does not inhibit fluorescence, even in the solid-state. Conductivity of the films was measured using a four-point probe and resulted in conductivities ranging from 12 S/cm for the 1:1 ZnQ_2-copolymer to 3.6 S/cm for the 1:20 ZnQ_2-copolymers. The results obtained from these experiments suggested that the ZnQ_2-polymer were able to support a current, which indicates these materials are useful in electroluminescent devices.

Definitions

In order to more clearly define the terms used herein, the following definitions are provided. To the extent that any definition or usage provided by any document incorporated herein by reference conflicts with the definition or usage provided herein, the definition or usage provided herein controls.

As used herein, the terms M^o, moiety, M^o-containing moiety, and the like refer to a chemical moiety which comprises an M^o residue, an M^o-like residue, a functionalized M^o, residue, a functionalized M^o-like residue, or similar structures. Thus, M^o-derived moieties constitute that portion of the M^o-functionalized molecule, monomer, or polymer that includes the M^o core group, regardless of the functionalization of the 8-hydroquinoline ligands and regardless of the heteroatom substitutions within the 8-hydroxyquinoline ligands.

The term 8-hydroxyquinoline residue is used to refer to, among other things, an 8-hydroxyquinoline ligand that can be non-functionalized; functionalized with at least one electron-donating group, at least one electron-withdrawing group, or a combination thereof; can be deprotonated; can be partially hydrogenated; and the like; or any combination of these. In the usual sense, the 8-hydroxyquinoline residue of this invention comprises a deprotonated 8-hydroxyquinoline, therefore M^o-containing monomers and polymers refer to metal (M) complexes in the n° oxidation state. This term is also used to refer to 8-hydroxyquinoline-like ligands such as, for example, ligands in which either another heteroatom is present in one of the 6-membered rings of the 8-hydroquinoline ligand, or a partially hydrogenated 8-hydroxyquinoline-like ligand. Examples of this type 8-hydroxyquinoline residue include, but are not limited to, the Naph and Quinox (also termed Quix) ligands illustrated in FIG. 3. This term also refers to 8-hydroxyquinoline ligands, or their heteroatom substituted analogs, that can be functionalized with at least one group independently selected from: a hydrocarbyl group, an oxygen group, a sulfur group, a nitrogen group, a phosphorus group, an arsenic group, a carbon group, a silicon group, a germanium group, a tin group, a lead group, a boron group, an aluminum group, an inorganic group, an organometallic group, or a substituted analog thereof, any one of which having from 1 to about 30 carbon atoms; a halide; a hydrogen; or any combination thereof.

The terms polymerizable moiety, polymerizable unit, polymerizable residue, and the like refer to a chemical moiety containing a polymerizable functional group. Examples of polymerizable functional groups include, but are not limited to, alkenes, alkynes, butadienes, and the like, although viable polymerizable functional groups depending upon factors that include, but are not limited to, the polymerization method, polymerization catalyst, monomer containing that polymerizable functional group, and the like. Examples of polymerizable moieties, units, residues, and the like, include, but are not limited to nortereone, norbornadiene, cyclopentene, cyclooctene, cyclooctadiene, or functionalized analogs thereof.

EXAMPLES

The present invention is further illustrated by the following examples, which are not to be construed in any way as imposing limitations upon the scope thereof. On the contrary, it is to be clearly understood that resort may be had to various other embodiments, modifications, and equivalents thereof which, after reading the description herein, may suggest themselves to one of ordinary skill in the art without departing from the spirit of the present invention or the scope of the appended claims.

Example 1

General Synthetic and Characterization Details

Unless otherwise specified, all chemicals were purchased from Acros Organics or Aldrich and used without further purification. All reactions were performed in atmospheric conditions unless otherwise noted. Flash column chromatography was carried out on silica gel 60, 230–400 mesh (Whatman or Sorbent Tech). The 1H (100 MHz) NMR spectra were recorded at 300 (75 MHz) on a Varian Mercury 300 spectrometer. Chemical shifts are reported in ppm on the δ scale relative to the solvent residual proton signal. Mass spectra were obtained on a Micromass Quattro LC spectrometer or a VG-70se spectrometer. Elemental analyses were performed on a Perkin-Elmer CBN9/S0 Analyzer Series II 2400.

Differential scanning calorimetry (DSC) was performed under nitrogen using either a Perkin-Elmer DSC 7 equipped with an Intracooler II device, wherein the temperature program provided heating and cooling cycles between 0° C. and 200° C. at 20° C./min, or provided heating and cooling cycles between -30° C. and 150° C. at 10° C./min. Differ-
ent scanning calorimetry (DSC) was also performed under nitrogen using a Netzsch STA 409 PG DSC coupled with a Netzsch TG 209 thermal gravimeter analyzer, wherein the temperature program provided a heating rate of 20° C/min from room temperature up to 800° C. Thermogravimetric analysis (TGA) measurements were also performed using Netzsch TG 209 from 30 to 500° C. at 20° C/min.

For some samples, gel permeation chromatography (GPC) analyses were carried out using a Waters 1525 binary pump coupled to a Waters 2414 refractive index detector. The GPC was calibrated using polystyrene standards on a Waters Styragel® HR 4 and HR 5E column set with CH2Cl2 as an eluent. For other samples, gel permeation chromatography (GPC) analyses were carried out using a Waters 1525 binary pump coupled to a Waters 410 refractive index detector. The GPC was calibrated using polystyrene standards on an American Polymer Standards 10k particle size, linear mixed bed packing columns set with CH2Cl2 as an eluent.

The UV/Visible spectroscopy were obtained on a Perkins-Elmer Lambda 19 UV/VIS/NIR Spectrometer. The fluorescence spectra were obtained on a Spex Fluorolog Spectrofluorometer. Ellipsometry measurements were taken on a J. A. Woollam Co. Inc. Spectroscopic Ellipsometer, M-2000V1.

Example 2

Preparation of 6-Bicyclo[2.2.1]hept-5-en-2-yl-hexylamine (4)

A solution of the nitrile 3 (1.052 g, 0.005 mol) in diethyl ether was added dropwise to a LiAlH4 suspension (0.43 g, 0.011 mol in 40 mL diethyl ether) at 0°C. The mixture was allowed to warm to room temperature over a period of an hour, refluxed for 30 minutes at room temperature. Water was added to neutralize any excess LiAlH4. The ether layer was washed with water, 20% NaOH, brine, and dried over Na2SO4. The ether was removed to give a pale yellow liquid, which needed no further purification (0.726 g 67%). 1H NMR (300 MHz, CDCl3) δ 6.07 (1H endo, dd, J=7.24, 5.49); 2.70 (2H, t, J=7.14); 1.94–1.74 (2H, m); 1.43–0.99 (12H, m); 0.46–0.40 (1H, m). 13C NMR (75 MHz, CDCl3) δ 133.2; 132.6; 128.0; 121.8; 127.4; 126.8; 117.0; 112.4; 110.2; 136.3; 133.4; 132.8; 128.7; 126.8; 121.8; 109.2; 51.2; 50.0; 49.7; 45.5; 42.7; 38.9; 34.9; 32.6; 29.9; 28.8; 27.1. HRMS (EI): calcd for C23H30N2O [M]+ 193.1832, found 193.1852.

Example 3

Preparation of 5-[6-Bicyclo[2.2.1]hept-5-en-2-yl-hexylamino]-methyl]-quinolin-8-ol (7)

Amine 4 (0.726 g, 0.00376 mol) and 5-formyl-8-hydroxyquinoline 6 (0.650 g, 0.00376 mol) were dissolved in 40 mL of benzene and refluxed for 18 hours. After cooling, the solvent was removed under reduced pressure to yield the product as an orange solid (1.308 g, 100%). 1H NMR (300 MHz, CDCl3) δ 89.75 (1H, dd, J=8.79, 1.64); 8.81 (1H, dd, J=1.64, 4.39); 8.59 (1H, s); 7.69 (1H, d, J=8.24); 7.56 (1H, dd, J=4.39, 8.79); 7.19 (1H, d, J=7.69); 6.10 (1H endo, dd, J=2.74, 5.49); 6.06–5.99 (2H exo, m); 5.91 (1H endo, dd, J=2.74, 5.94); 3.67 (2H, t, J=7.14); 2.74 (2H, s); 1.99–1.69 (4H, m); 1.42–1.01 (12H, m); 0.50–0.44 (1H, m). 13C NMR (75 MHz, CDCl3) δ 160.8; 154.2; 148.1; 138.4; 137.0; 135.3; 133.0; 132.6; 127.0; 123.3; 123.2; 109.2; 62.9; 49.7; 45.6; 42.7; 38.9; 34.9; 32.6; 31.4; 29.9; 28.8; 27.6. HRMS (EI): calcd for C33H36N3O7 [M]+ 548.2201, found 548.2186.

Example 4

Preparation of 5-[6-Bicyclo[2.2.1]hept-5-en-2-yl-hexylamino]-methyl]-quinolin-8-ol (8)

Imine 7 was dissolved in 50 mL of dry methanol and 1 equivalent of NaBH4 (0.136 g, 0.0036 mol) was added in small increments. After the addition was complete, the solution was allowed to stir for 10 minutes at room temperature. The solution was diluted with water and extracted three times with 20 mL of methylene chloride. The combined organic layers were washed with water, NaHCO3, brine, and dried over Na2SO4. The solvent was removed under reduced pressure to yield a brown liquid. Purification by column chromatography (silica gel, 4:1 hexanes/ethyl acetate, then pure ethyl acetate, then 5% methanol in ethyl acetate) gave the product as a pale yellow solid (0.658 g, 50%). 1H NMR (300 MHz, CDCl3) δ 88.75 (1H, dd, J=1.09, 4.39); 8.51 (1H, dd, J=1.09, 8.24); 7.46 (1H, dd, J=4.39, 8.24); 7.38 (1H, d, J=7.69); 7.08 (1H, d, J=7.69); 6.11 (1H endo, dd, J=2.74, 5.49); 6.06–5.99 (2H exo, m); 5.90 (1H endo, dd, J=2.74, 5.49); 4.10 (1H, s); 2.73 (2H, s); 2.71 (2H, t, J=7.14); 1.99–1.02 (12H, m); 0.49–0.43 (1H, m). 13C NMR (75 MHz, CDCl3) δ 151.8; 147.6; 137.0; 136.3; 133.4; 132.8; 128.7; 126.8; 121.8; 109.2; 51.2; 50.0; 49.7; 45.5; 42.7; 38.9; 34.9; 32.6; 30.2; 29.9; 28.8; 27.5. Anal. Calcd for C33H36N3O7: C, 78.88; H, 8.63; N, 8.00. Found C: 78.79, H: 8.72, N: 8.00.

Example 5

Preparation of the Alq3-functionalized monomer 9

The formation of the Alq3-functionalized monomer 9 was achieved by adding monomer 8, dissolved in 10 mL of dry THF, dropwise to ten equivalents of triethylaluminum, dissolved in 10 mL of dry THF, and stirring under argon for 2 hours. Then 20 equivalents of 8-hydroxyquinoline, dissolved in 10 mL of THF, was added dropwise to the monomer solution, and the solution was stirred overnight under argon. Any precipitate that formed was filtered off and the solvent was removed to yield a bright yellow solid. This product was used without further purification in the polymerization procedure.
Preparation of 5-Nonyl-bicyclo[2.2.1]hept-2-ene (12)

An oven-dried 3-neck round bottom flask was charged with magnesium turnings (0.809 g, 0.033 mol) and 40 mL of dry THF. 5-Bromomethyl norbornene (6.001 g, 0.032 mol) was added dropwise at room temperature. The mixture was then heated to 50°C for 18 hours. In a separate flask, 10 mL of dry THF, Li₂CuCl₄ (5 mL, 0.0005 mol), and 1-bromooctane (6 mL, 0.035 mol) were combined and placed in a -10°C ice bath. The Grignard reagent, which was transferred via cannula into an addition funnel, was added dropwise to the cooled solution. After the addition was complete, the solution was warmed to room temperature and stirred for 18 hours. The solution was diluted with ether, washed with Na₂S₀₄, brine, and dried over MgSO₄. The solvent was removed to yield a yellow solid 14.

Preparation of 5-(6-Bicyclo[2.2.1]hept-2-yl-hexylamino)-methyl]-8-quinolinato-(dihydroxy)-aluminum (14).

The monomer 5-(6-Bicyclo[2.2.1]hept-2-yl-hexylamino)-methyl]-quinolin-8-ol (8) (0.025 g, 0.07 mmol) was dissolved in 5 mL benzene, and added dropwise to a solution of triethylalumina (0.04 mL, 0.07 mmol) in 10 mL benzene, Scheme 5. The reaction was stirred for 2 hours under argon, the precipitate was filtered off, and the solvent was removed to yield a yellow solid 14 (0.03 g, 96% yield). ¹H NMR (300 MHz, CDCl₃) ð 66.12 (1H endo, dd, J=2.74, 5.49); 6.09–5.99 (2H exo, m); 5.93 (1H endo, dd, J=3.74, 5.49); 2.75 (1H, s); 1.98–1.78 (2H, m); 1.40–1.07 (18H, m); 0.89 (3H, t, J=6.05); 0.52–0.45 (1H, m). ¹³C NMR (75 MHz, CDCl₃) δ 137.0; 132.6; 51.2; 49.7; 45.6; 42.7; 38.9; 35.0; 32.6; 32.1; 30.1; 29.9; 29.8; 29.5; 28.9; 22.9; 14.3.

Example 8

Preparation of 5-(6-Bicyclo[2.2.1]hept-2-yl-hexylamino)-methyl]-8-quinolinato-(dihydroxy)-aluminum (15a–15j)

Two equivalents of a modified 8-hydroxyquinoline ligand X, examples of which are shown in FIG. 3 and which are abbreviated as X in Scheme 5, were dissolved in benzene and added dropwise to one equivalent of the dihydroxy monomer 14 dissolved in 10 mL of benzene. The solution was allowed to stir under argon for two hours, followed by the removal of the solvent to yield a solid ranging in color from bright yellow to dark orange. The exceptions to this procedure are when X was 4-hydroxy-1,5-naphthyridine (Naph) or 8-hydroxyquinoline-5-sulfonic acid. (SO₃H) These compounds were dissolved in DMSO, while monomer 14 was dissolved in THF.

The resulting functionalized Alq₃-containing monomers provided by this procedure are shown in Table 1.

Example 9

General Polymerization Procedure

Monomers 9, 15 (15a–15j), and 12, as needed, were dissolved in chloroform in the desired ratio, the ruthenium catalyst 11 was dissolved in chloroform, and both solutions were combined. The polymerizations were monitored by NMR and were complete within 12 hours. All polymers were purified by repeated precipitation into methanol. Again, the exceptions to this procedure are when the functionalized monomer X was 4-hydroxy-1,5-naphthyridine or the 8-hydroxyquinoline-5-sulfonic acid. In these cases, the AlqX₂-monomer Naph and SO₃H were dissolved in a 1:1 ratio of DMSO/chloroform.

Example 10

Solution Photoluminescence Studies

Approximately 5 mg of each of the polymers shown in Table 5 was dissolved in 10 mL of chloroform. Dilutions were made as needed. UV/Visible and fluorescence measurements were taken in a 1.0 cm quartz cell.

Example 11

Thin Film Fabrication and Characterization

The concentrations of the polymers in solution were varied from 15–100 mg of polymer per mL of chloroform. One drop of each solution was dropped onto a quartz slide spinning at 2000 rpm. The polymer solutions that showed the highest fluorescence intensity in the solid-state ranged from 30-50 mg/mL. The films made for the ellipsometry experiment were prepared in a similar manner using gold-coated glass slides (100 nm of Au) instead of quartz slides. The film thicknesses were measured by ellipsometry by collecting data every 5° from 65° to 75° and were fitted using a Cauchy film on gold model. The resistances of the films were measured using a Keithley 196 system and an Ai (15a-15j) alessi four-point probe. The probe was lowered until it came in contact with the surface of the films and the resistance was recorded. Conductivity was determined based on the equation: \( \sigma = 0.221 (R*r)^{-1} \), where \( R \) is the resistance in ohms, \( t \) is the thickness of the film in centimeters, and \( \sigma \) is the conductivity in Siemens/cm. (See: Smits, F. M. Bell Syst. Tech. J. 1958, 710–718.)
Distances of the films were measured using a Keithley 196 that showed the highest fluorescence intensity in the solid.

Example 13

Preparation of 5-[6-Bicyclo[2.2.1]hept-5-en-2-yl-hexylamino]-methyl]-8-quinolinato-(Zigand X)-zinc (2).

Monomer 8 (0.025 g, 0.07 mmol) was dissolved in 5 mL dry benzene and added dropwise to a solution of diethylzinc (0.04 mL, 0.07 mmol) in 10 mL dry benzene. The reaction was stirred for two hours under argon. The resulting precipitate was filtered off and the solvent was removed to yield a solid benzene and added dropwise to one equivalent of the modified 8-hydroxyquinoline ligands X was dissolved in 10 mL dry benzene and added dropwise to one equivalent of the zinc-monomer, dissolved in 10 mL of dry benzene. The solution was allowed to stir under argon for two hours, followed by the removal of the solvent to yield a solid, yielding a yellow solid which was used without further purification (0.03 g, 96% yield). One equivalent of the modified 8-hydroxyquinoline ligands X was dissolved in 10 mL dry benzene and added dropwise to one equivalent of the zinc-monomer, dissolved in 10 mL of dry benzene. The solution was allowed to stir under argon for two hours, followed by the removal of the solvent to yield a solid ranging in color from bright yellow to dark orange.

Example 14

Thin Film Fabrication and Characterization of Znq2-Co-polymers

The concentrations of the Znq-containing polymers in solution were varied from 15–100 mg of polymer per mL of dry chloroform. One drop of each solution was dropped onto a quartz slide spinning at 2000 rpm. The polymer solutions that showed the highest fluorescence intensity in the solid-state ranged from 30–50 mg/mL. The films made for the ellipsometry experiment were prepared in a similar manner using gold-coated glass slides (100 nm of Au) instead of quartz slides. The film thicknesses were measured by ellipsometry by collecting data every 5° from 65° to 75° and were fitted using a Cauchy film on gold model. The resistance was recorded. Conductivity was determined based on the equation: \( \sigma = 0.221 \frac{R^*t}{f} \), where \( R \) is the resistance in ohms, \( t \) is the thickness of the film in centimeters, and \( \sigma \) is the conductivity in Siemens/cm².

What is claimed is:

1. An Alq3-functionalized compound comprising an olefinic, acetylenic, or diolefinic polymerizable moiety and an Alq3-moiety, wherein \( q \) in each instance, comprises an 8-hydroxyquinoline residue.

2. The Alq3-functionalized compound of claim 1, wherein the Alq3-moiety is functionalized with at least one electron-donating group, at least one electron-withdrawing group, or a combination thereof.

3. The Alq3-functionalized compound of claim 1, wherein the Alq3-moiety is functionalized with at least one group independently selected from: a hydrocarbyl group, an oxygen group, a sulfur group, a nitrogen group, a phosphorus group, an arsenic group, a carbon group, a silicon group, a germanium group, a tin group, a lead group, a boron group, an aluminum group, an inorganic group, an organometallic group, or a substituted analog thereof, any one of which having from 1 to about 30 carbon atoms; a halide; hydrogen; or any combination thereof.

4. The Alq3-functionalized compound of claim 1, wherein the compound has the formula
6. A light-emitting diode comprising the polymerization product of the Alq₃-functionalized compound of claim 1.

7. A composition comprising the polymerization product of an Alq₃-functionalized monomer, wherein the Alq₃-functionalized monomer comprises an olefinic, acetylenic, or dieltefinic polymerizable moiety and an Alq₃-moiety, and wherein q, in each instance, comprises an 8-hydroxyquinoline residue.

8. The composition of claim 7, wherein the polymerization product is substantially non-crosslinked.

9. The composition of claim 7, wherein the Alq₃-moiety is functionalized with at least one electron-donating group and an Alq₃-moiety, and wherein the chemical moiety is norbornene.

10. The composition of claim 7, wherein the polymerizable moiety is norbornene.

11. A light-emitting diode comprising the composition of claim 7.

12. A composition comprising the polymerization product of at least one Alq₃-functionalized monomer and at least one comonomer, wherein the Alq₃-functionalized monomer comprises an olefinic, acetylenic, or dieltefinic polymerizable moiety and an Alq₃-moiety, and wherein q, in each instance, comprises an 8-hydroxyquinoline residue.

13. The composition of claim 12, wherein the polymerizable moiety is norbornene, norbornadiene, cyclopentene, cyclooctene, cyclooctadiene, or a substituted analog thereof.

14. The composition of claim 12, wherein the polymerizable moiety is norbornene or a substituted analog thereof.

15. The composition of claim 12, wherein the Alq₃-moiety is functionalized with at least one electron-donating group, at least one electron-donating group, and at least one electron-donating group, or a combination thereof.

16. The composition of claim 12, wherein the Alq₃-moiety is functionalized with at least one group independently selected from a hydrocarbyl group, an oxygen group, a nitrogen group, a phosphorus group, an arsenic group, a carbon group, a silicon group, a germanium group, a tin group, a boron group, an aluminum group, an inorganic group, an organometallic group, or a substituted analog thereof, any one of which having up to about 30 carbon atoms; and wherein X, in each instance, is independently selected from H or a substituted or unsubstituted hydrocarbyl group having from 1 to about 30 carbon atoms.

17. The composition of claim 12, wherein the Alq₃-moiety is functionalized with at least one group independently selected from a hydrocarbyl group, an oxygen group, a nitrogen group, a phosphorus group, an arsenic group, a carbon group, a silicon group, a germanium group, a tin group, a boron group, an aluminum group, an inorganic group, an organometallic group, or a substituted analog thereof, any one of which having up to about 30 carbon atoms.

18. The composition of claim 12, wherein the Alq₃-moiety is functionalized with at least one group independently selected from a hydrocarbyl group, an oxygen group, a nitrogen group, a phosphorus group, an arsenic group, a carbon group, a silicon group, a germanium group, a tin group, a boron group, an aluminum group, an inorganic group, an organometallic group, or a substituted analog thereof, any one of which having up to about 30 carbon atoms.

19. The composition of claim 12, wherein the Alq₃-moiety is functionalized with at least one group independently selected from a hydrocarbyl group, an oxygen group, a nitrogen group, a phosphorus group, an arsenic group, a carbon group, a silicon group, a germanium group, a tin group, a boron group, an aluminum group, an inorganic group, an organometallic group, or a substituted analog thereof, any one of which having up to about 30 carbon atoms.

20. The composition of claim 12, wherein the Alq₃-functionalized monomer further comprises a chemical spacer between the polymerizable moiety and the Alq₃-moiety, having between 1 and about 30 carbon atoms.

21. The composition of claim 12, wherein the chemical spacer is selected from: (CH₂)₂NHCH₂- or (CH₂)₃NR-CH₂-, wherein n is from 1 to about 12, and R is selected from a hydrocarbyl or substituted hydrocarbyl group having from 1 to about 30 carbon atoms.

22. The composition of claim 12, wherein the polymerization product comprises a block copolymer or a random copolymer.

23. The composition of claim 12, wherein the Alq₃-functionalized monomer is selected from:Phi, Cl, Br, I, H, OR, -SR, or -NR₂; wherein R₁ and R₂ are independently selected from: a hydrocarbyl group, an oxygen group, a nitrogen group, a phosphorus group, an arsenic group, a carbon group, a silicon group, a germanium group, a tin group, a boron group, an aluminum group, an inorganic group, an organometallic group, or a substituted analog thereof, any one of which having up to about 30 carbon atoms.
or any combination thereof.

24. The composition of claim 12, wherein the at least one comonomer comprises a compound with the formula

![Chemical Structure](image-url)

wherein n is an integer from 1 to about 12.

25. The composition of claim 12, wherein the polymerization product is characterized by a polydispersity (Mw/Mn) from about 1.5 to about 1.8.

26. A light-emitting diode comprising the composition of claim 12.

27. A method of making an Alq₃-functionalized polymer comprising:

polymerizing an Alq₃-functionalized monomer in the presence or absence of at least one comonomer, wherein the Alq₃-functionalized monomer comprises an olefinic, acetylenic, or diolefinic polymerizable moiety and an Alq₃-moiety; and wherein q, in each instance, comprises an 8-hydroxyquinoline residue.

28. The method of claim 27, wherein the Alq₃-functionalized monomer is polymerized in the presence of at least one comonomer.

29. The method of claim 27, wherein the Alq₃-functionalized monomer is polymerized in the presence of at least one comonomer, and wherein the molar ratio of Alq₃-functionalized monomer to comonomer is from about 1:1 to about 1:100.

30. The method of claim 27, wherein the Alq₃-functionalized monomer is polymerized in the presence of at least one comonomer comprising

![Chemical Structure](image-url)

wherein n is an integer from 1 to about 12.

31. The method of claim 27, wherein the polymerizable moiety of the Alq₃-functionalized monomer is selected from norbornene, norbomadiene, cyclopentene, cyclooctene, cyclooctadiene, or a functionalized analog thereof.
41. The method of claim 40, wherein the chemical spacer is selected from \(-(\text{CH}_2)_n\text{NHCH}_2\) or \(-(\text{CH}_2)_n\text{NR}_1\text{CH}_2\)-, wherein \(n\) is from 1 to about 12, and \(R_1\) is selected from a hydrocarbyl or substituted hydrocarbyl having from 1 to about 30 carbon atoms.

42. The method of claim 27, wherein the polymerization product comprises a block copolymer.

43. The method of claim 27, wherein the \(\text{Alq}_3\)-functionalized monomer is selected from:
44. A method of functionalizing a polymer with an Alq₃ moiety, comprising:

providing an Alq₃-functionalized monomer; and

polymerizing an Alq₃-functionalized monomer in the presence or absence of at least one comonomer;

wherein the Alq₃-functionalized monomer comprises an olefinic, acetylenic, or diolefinic polymerizable moiety
and an Alq₃-moiety; and

combination thereof.

45. A compound having the formula

\[
\begin{align*}
\text{Ph} & \quad \text{N} \\
\text{O} & \quad \text{N} \\
\text{Ph} & \quad \text{O}
\end{align*}
\]

wherein: n is from 1 to about 12; and R¹ is selected from H, a hydrocarbyl, or a substituted hydrocarbyl having from 1 to about 30 carbon atoms.

46. A composition comprising the polymerization product of:

1) a compound having the formula

\[
\begin{align*}
\text{Ph} & \quad \text{N} \\
\text{O} & \quad \text{N} \\
\text{Ph} & \quad \text{O}
\end{align*}
\]

wherein: n is from 1 to about 12; and R¹ is selected from H, a hydrocarbyl, or a substituted hydrocarbyl having from 1 to about 30 carbon atoms; and

2) at least one optional comonomer having up to about 30 carbon atoms.

47. The composition of claim 46, wherein the at least one comonomer comprises a compound with the formula

\[
\begin{align*}
\text{Ph} & \quad \text{N} \\
\text{O} & \quad \text{N} \\
\text{Ph} & \quad \text{O}
\end{align*}
\]

wherein n is an integer from 1 to about 12.

48. An Mqₙ,-functionalized compound comprising an olefinic, acetylenic, or diolefinic polymerizable moiety and an Mqₙ-moiey, wherein q, in each instance, comprises an 8-hydroxyquinoline residue, and M is selected from Mg, Zn, Al, Ga, or In; and n is selected from 2 or 3 according to the valence of the metal.

49. The Mqₙ,-functionalized compound of claim 48, wherein the Mqₙ-moiey is functionalized with at least one electron-donating group, at least one electron-withdrawing group, or a combination thereof.

50. The Mqₙ,-functionalized compound of claim 48, wherein the Mqₙ-moiey is functionalized with at least one group independently selected from: a hydrocarbyl group, an oxygen group, a sulfur group, a nitrogen group, a phosphorus group, an arsenic group, a carbon group, a silicon group, a germanium group, a tin group, a lead group, a boron group, an aluminum group, an inorganic group, an organometallic group, or a substituted analog thereof, any one of which having from 1 to about 30 carbon atoms; a halide; hydrogen; or any combination thereof.

51. The Mqₙ,-functionalized compound of claim 48, wherein the compound has the formula

\[
\begin{align*}
\text{Ph} & \quad \text{N} \\
\text{O} & \quad \text{N} \\
\text{Ph} & \quad \text{O}
\end{align*}
\]
wherein Y and Z are independently selected from: 
- Cl, Br, I, R¹, CR³=O, CH=CHC(O)₃, 
- C(R)OR¹, C(O)OR¹, CN, C(NR)R¹, 
- C(NR)OR¹, CH₂C₆H₄X, CH₂C₆H₃X, 
- CH₂C₆H₃R², CH₂C₆H₄R², CH₂C₆H₄X, 
- CH₂CH₂C₆H₄X, CH₂CH₂C₆H₃X, 
- CH₂CH₂C₆H₃R², CH₂CH₂C₆H₄R², 
- OCO(R)R¹, SiR³, OSiR², OR¹, 
- SiR₃, OSiR₂, OR¹, 
- N₃, NR=CR², NR=NR², 
- OR¹, OSO₂R², SCN, SO₂R², PR², 
- PX², P(O)OR², P(OR²)₂, P(O)(OR²)₂, 
- OSiR³, OPR², OAIR², 
- AR², As(O)R⁴, As(O)OR⁴, SnR³, OSnR³, 
- SnX³, OSnX³, BrX², BX², 
- SnI³, OSnI³, 
- OAlX², OSiX³, OPX², S, OSO₂X, AsX², 
- As(O)X²; 

wherein R¹, in each instance, is independently selected from H or a substituted or unsubstituted hydrocarbyl group having from 1 to about 30 carbon atoms; 
wherein X, in each instance, is independently selected from F, Cl, Br, I, H, OR¹, -SR¹, or NR²; and 
wherein q and m are independently selected from an integer from 0 to 3.

52. The Mqₓₜ功能性化合物 of claim 48, wherein: 
the compound has the formula 

\[
\begin{align*}
\text{(CH₃)₃NHHCl} & \quad \text{CH} \quad \text{O} \\
\text{O} & \quad \text{Zn} & \quad \text{X} \\
\end{align*}
\]

X is selected from an 8-hydroxyquinoline residue selected 

and wherein the 8-hydroxyquinoline residue has been deprotonated.

53. A method of making a Mqₓₜ功能性聚合物, comprising: 
preparing a qₓ功能性单体; 
polymerizing the monomer in the presence or absence of a comonomer to form a qₓ功能性聚合物; and 
reacting the polymer with a metal complex to form a Mqₓₜ功能性聚合物; 
wherein M is selected from Mg, Zn, Al, Ga, or In; and n is selected from 2 or 3 according to the valence of the metal.
